CONVEX SOLUTIONS
TO THE MEAN CURVATURE FLOW

ABSTRACT. In this paper we study the classification of ancient convex solutions to the mean curvature flow in $\mathbb{R}^{n+1}$. An open problem related to the classification of type II singularities is whether a convex translating solution is $k$-rotationally symmetric for some integer $2 \leq k \leq n$, namely whether its level set is a sphere or cylinder $S^{k-1} \times \mathbb{R}^{n-k}$. In this paper we give an affirmative answer for entire solutions in dimension 2. In high dimensions we prove that there exist non-rotationally symmetric, entire convex translating solutions, but the blow-down in space of any entire convex translating solution is $k$-rotationally symmetric. We also prove that the blow-down in space-time of an ancient convex solution which sweeps the whole space $\mathbb{R}^{n+1}$ is a shrinking sphere or cylinder.

1. Introduction

Convex solutions arise in the study of singularities of the mean curvature flow. To study the geometric behavior at singularities one needs to classify such solutions. In this paper\(^1\) we study the classification, or more precisely the geometric asymptotic behavior, of general ancient convex solutions, including the convex translating solutions arising at type II singularities [14,15] and the ancient convex solutions arising at general singularities [28].

It was proved by Huisken-Sinestrari [14, 15] that if $\mathcal{M}$ is a mean convex flow, namely a mean curvature flow with mean convex solution, in the Euclidean space $\mathbb{R}^{n+1}$, then the limit flow obtained by a proper blow-up procedure near type II singular points is a convex translating solution (also called soliton), that is in an appropriate coordinate system a mean curvature flow of the form $\mathcal{M}' = \{(x, u(x) + t) \in \mathbb{R}^{n+1} : x \in \mathbb{R}^n, t \in \mathbb{R}\}$, where $u$ is a complete convex solution to the mean curvature equation

\begin{equation}
\text{div}\left(\frac{Du}{\sqrt{1 + |Du|^2}}\right) = \frac{1}{\sqrt{1 + |Du|^2}}.
\end{equation}

\(^1\)This is a revised version of the paper arXiv:math.DG/0404326. All results and the ideas of proofs are the same. The main change is the proof of the growth estimate (1.5) in Section 2. In this new version we divide it into two parts. We first prove it for dimension 2, then prove it for high dimensions.
Translating solutions play a similar role for the investigation of asymptotic behavior of type II singularities as self-similar solutions for type I singularities. It is known that a convex self-similar solution must be a shrinking sphere or cylinder [13]. For convex translating solutions there is a well known conjecture among researchers in this area, which is explicitly formulated, for example in [28], which asserts that if \( u \) is a complete convex solution of (1.1), then the level sets \( \{ u = \text{const} \} \) are spheres or cylinders. This Bernstein type problem attracted attention in recent years, as it is crucial for a classification of type II singularities of the mean convex flow. In this paper we prove the conjecture is true for entire solutions in dimension two (Theorem 1.1) and false in higher dimensions (Theorem 1.2).

In this paper we also study the classification of general ancient convex solutions to the mean curvature flow. In [28] White proved that any limit flow to the mean convex flow in \( \mathbb{R}^{n+1} \) for \( n < 7 \), or any special limit flow, namely blowup solution before first time singularity for \( n \geq 7 \), is an ancient convex solution, namely at any time the solution is a convex hypersurface. We prove that an ancient convex solution is convex in space-time (Proposition 4.1); and that the parabolic blow-down in space-time of any entire, ancient convex solution, and the blow-down in space of any entire convex translating solution, is a shrinking sphere or cylinder (Theorem 1.3). This result corresponds to Perelman’s classification of ancient \( \kappa \)-noncollapsing solutions with nonnegative sectional curvature to the 3-dimensional Ricci flow [22], see §6.

To study the above two problems, we will consider the following more general equation

\[
\mathcal{L}_\sigma[u] =: \sum_{i,j=1}^{n} (\delta_{ij} - \frac{u_i u_j}{\sigma + |Du|^2}) u_{ij} = 1,
\]

where \( \sigma \in [0, 1] \) is a constant. If \( u \) is a convex solution of (1.2), then \( u + t \), as a function of \((x, t) \in \mathbb{R}^n \times \mathbb{R}\), is a translating solution to the flow

\[
u_t = \sqrt{\sigma + |Du|^2} \text{div} \left( \frac{Du}{\sqrt{\sigma + |Du|^2}} \right).
\]

When \( \sigma = 1 \), equation (1.2) is exactly the mean curvature equation (1.1), and (1.3) is the non-parametrized mean curvature flow. When \( \sigma = 0 \), (1.3) is the level set flow. That is if \( u \) is a solution of (1.2) with \( \sigma = 0 \), the level set \( \{ u = -t \} \), where \(-\infty < t < -\inf u \), evolves by mean curvature.

Conversely, if a family of convex hypersurfaces \( \mathcal{M} = \{ \mathcal{M}_t \} \), with time slice \( \mathcal{M}_t \), evolves by mean curvature, then \( \mathcal{M} \) can be represented as a graph of \( u \) in the space-time \( \mathbb{R}^{n+1} \times \mathbb{R}^1 \) with \( x_{n+2} = -t \), and the function \( u \) satisfies (1.2) with \( \sigma = 0 \). We will show that the function \( u \) itself is convex (Proposition 4.1). Therefore for both problems it suffices to study the classification of convex solutions to equation (1.2).
We say a solution to the mean curvature flow is *ancient* if it exists from time $-\infty$. We say a solution $u$ of (1.2) is *complete* if its graph is a complete hypersurface in $\mathbb{R}^{n+1}$, and $u$ is an *entire* solution if it is defined in the whole space $\mathbb{R}^n$. Accordingly an ancient convex solution $M$ to the mean curvature flow in $\mathbb{R}^{n+1}$ is an entire solution if $M$ is an entire graph in space-time $\mathbb{R}^{n+1} \times \mathbb{R}^1$, which is equivalent to saying that the flow $M$ sweeps the whole space $\mathbb{R}^{n+1}$. We say $u$ is $k$-*rotationally symmetric* if there exists an integer $1 \leq k \leq n$ such that in an appropriate coordinate system, $u$ is rotationally symmetric with respect to $x_1, \ldots, x_k$ and is independent of $x_{k+1}, \ldots, x_n$. Therefore a function $u$ is $k$-rotationally symmetric if and only if its level sets are spheres ($k = n$) or cylinders ($k < n$).

For other related terminologies we refer the reader to [15, 28]. For any $1 \leq k \leq n$, there is a $k$-rotationally symmetric convex solution of (1.1), which is unique up to orthogonal transformations. When $n = 1$, the unique complete convex solution of (1.1) is the “grim reaper”, given by $u(x) = \log \sec x_1$. To exclude hyperplanes in this paper we always consider convex solution with positive mean curvature.

The results in this paper can be summarized in the following theorems.

**Theorem 1.1.** If $n = 2$, then any entire convex solution to (1.2) must be rotationally symmetric in an appropriate coordinate system.

From Theorem 1.1 we obtain

**Corollary 1.1.** A convex translating solution to the mean curvature flow must be rotationally symmetric if it is a limit flow to a mean convex flow in $\mathbb{R}^3$.

**Theorem 1.2.** For any dimension $n \geq 2$ and $1 \leq k \leq n$, there exist complete convex solutions, defined in strip regions, to equation (1.2) which are not $k$-rotationally symmetric. If $n \geq 3$, there exist entire convex solutions to (1.2) which are not $k$-rotationally symmetric.

Theorems 1.1 and 1.2 reflect a typical phenomenon, namely the Bernstein theorem is in general true in low dimensions and false in higher dimensions. See [26] for a brief discussion.

**Theorem 1.3.** Let $u$ be an entire convex solution of (1.2). Let $u_h(x) = h^{-1}u(\sqrt{h}x)$. Then there is an integer $2 \leq k \leq n$ such that after a rotation of the coordinate system for each $h$, $u_h$ converges to

$$\eta_k(x) = \frac{1}{2(k-1)} \sum_{i=1}^{k} x_i^2.$$  

The case $\sigma = 0$ of Theorems 1.1-1.3 describes the geometry of ancient convex solutions to the mean curvature flow, while the case $\sigma = 1$ of Theorems 1.1-1.3 resolves the problem on convex translating solutions. Note that if $u$ is a convex solution which is not defined in the whole space, then $u$ is defined in a convex strip region (Corollaries 2.1 and 2.2), and
it cannot be a blowup solution to the mean convex flow in general (Corollary 6.1). We also remark that in Theorem 1.3 we did not rule out the possibility that the axis of the cylinder-like level set \( \{ u_h = 1 \} \) may rotate slowly as \( h \to \infty \), as the convergence \( u_h \to \eta_k \) is uniform only on any compact sets.

As a limit flow at the first time singularity is convex, by Brakke’s regularity theorem, a blowup sequence converges smoothly on any compact sets to an ancient convex solution [28]. Therefore by the above classifications one may infer that if \( \mathcal{M} = \{ \mathcal{M}_t \} \) is a mean convex flow in \( \mathbb{R}^{n+1} \), \( n \geq 2 \), then \( \mathcal{M}_t \) satisfies a canonical neighborhood condition, similar to the assertion in [23] for the Ricci flow, at any point \( x_t \in \mathcal{M}_t \) with large mean curvature before the first time singularity. In particular if the mean curvature at \( x_t \) converges to infinity, then a proper scaling of \( \mathcal{M} \) at \( x_t \) converges along subsequences to shrinking spheres or cylinders. See discussions in §6.

Our proofs of the above theorems rely heavily on the convexity of solutions. To prove these theorems it suffices to consider the cases \( \sigma = 0 \) and \( \sigma = 1 \), as for any \( \sigma > 0 \), one can make the transform \( \hat{u}(x) = \frac{1}{\sigma} u(\sqrt{\sigma} x) \) to change equation (1.2) to the case \( \sigma = 1 \). A key estimate for the proof of Theorem 1.3 is that for any entire convex solution \( u \) of (1.2), there exists a positive constant \( C \) such that

\[
(1.5) \quad u(x) \leq C(1 + |x|^2) \quad \forall \ x \in \mathbb{R}^n.
\]

The constant \( C \) depends only on \( n \) and the upper bound of \( u(0) \) and \( |Du(0)| \). Note that (1.5) implies the compactness of the set of entire convex solutions to (1.2), see Corollary 2.3.

By Theorem 1.3 and estimate (1.5) we have, if \( n = 2 \),

\[
C_1 |x|^2 \leq u(x) \leq C_2 |x|^2
\]

for large \( |x| \). Hence the case \( \sigma = 0 \) of Theorem 1.1 follows immediately from the asymptotic estimates in [8]. For the case \( \sigma = 1 \) we will prove furthermore, by an iteration argument, that

\[
(1.6) \quad |u(x) - u_0(x)| = o(|x|) \quad \text{as} \quad |x| \to \infty,
\]

where \( u_0 \) is the radial solution of (1.1). We then conclude \( u = u_0 \) by a Liouville type theorem of Bernstein [2], which asserts that an entire solution \( w \) to an elliptic equation in \( \mathbb{R}^2 \) must be a constant if \( |w(x)| = o(|x|) \) at infinity [24].

The proof of Theorem 1.2 is different for the cases \( \sigma = 0 \) and \( \sigma = 1 \). For the case \( \sigma = 0 \), we consider the Dirichlet problem

\[
(1.7) \quad \begin{cases}
    \mathcal{L}_0[u] = 1 & \text{in} \ \Omega, \\
    u = 0 & \text{on} \ \partial \Omega,
\end{cases}
\]
where $\Omega$ is a bounded convex domain in $\mathbb{R}^n$ ($n \geq 2$). The existence and uniqueness of viscosity solutions to (1.7) can be found in [3,7]. We prove that there exists a sequence of bounded convex domains $\{\Omega_k\}$ such that $u_k + |\inf_{\Omega_k} u_k|$, where $u_k$ is the solution of (1.7) with $\Omega = \Omega_k$, converges to a complete convex solution $u$ of $\mathcal{L}_0[u] = 1$ of which the level set $\{x \in \mathbb{R}^n : u(x) = 1\}$ is not a sphere. To prove that $u$ is a complete convex solution we need the concavity of the function $\log(-u)$ (Lemma 4.1).

The concavity of $\log(-u)$ is still an open problem for the mean curvature equation (1.1). To construct a similar sequence of solutions $(u_k)$ for equation (1.1), we use the Legendre transform to convert the mean curvature equation (1.1) to a fully nonlinear equation for which the convexity is a natural condition for the ellipticity of the equation. Let $u$ be a smooth, uniformly convex function defined in a convex domain $\Omega \subset \mathbb{R}^n$. The Legendre transform of $u$, $u^*$, is a smooth, uniformly convex function defined in $\Omega^* = Du(\Omega)$, given by

$$u^*(y) = \sup\{x \cdot y - u(x) : x \in \Omega\}.$$  

The supremum is attained at the unique point $x$ such that $y = Du(x)$, and $u$ can be recovered from $u^*$ by the same Legendre transform. If $u$ is a convex solution of (1.1), $u^*$ satisfies the fully nonlinear equation

$$\det D^2 u^* = \sum (\delta_{ij} - \frac{y_i y_j}{1 + |y|^2}) F^{ij}[u^*],$$

where $\delta_{ij} = 1$ if $i = j$ and $\delta_{ij} = 0$ otherwise, and

$$F^{ij}[u^*] = \frac{\partial}{\partial r_{ij}} \det r \quad \text{at} \quad r = D^2 u^*.$$  

It is known that for any uniformly convex domain $\Omega$ and any smooth function $\varphi$ on $\partial\Omega$, (1.9) has a unique convex solution $u^*$ in $\Omega$ satisfying $u^* = \varphi$ on $\partial\Omega$, see Theorem 5.2. By Theorem 5.2 we can construct a sequence of convex solutions $(u_k^*)$ to (1.9), such that $(u_k)$, the Legendre transform of $(u_k^*)$, converges to a complete convex solution $u$ of (1.1) and the level set $\{x \in \mathbb{R}^n : u(x) = 1 + \inf u\}$ is not a sphere.

This paper is arranged as follows. In Section 2 we prove estimate (1.5) and Theorem 1.3. In Section 3 we prove Theorem 1.1. In Section 4 we prove the case $\sigma = 0$ of Theorem 1.2. The case $\sigma = 1$ of Theorem 1.2 will be proved in Section 5. The final Section 6 contains some applications. We first prove Corollary 1.1, then discuss implications of Theorem 1.3, and finally mention a few unsolved problems related to our Theorem 1.1-1.3.

Recent developments. A major advance, after the paper was finished in early 2003, has been made by Huisken and Sinestrari [29], in which they studied the mean curvature flow with surgeries of 2-convex hypersurfaces in $\mathbb{R}^{n+1}$ for $n \geq 3$. They proved that at any point with
large curvature, the hypersurface after normalization must be very close to the cylinder $S^{n-1} \times \mathbb{R}^1$ or a convex cap. Very recently, in another development, the author, together with Weimin Sheng [30], found a new proof for the following result of White [27,28], that is for the mean convex flow up to the first time singularity, a blow-up sequence converges along a subsequence to a convex mean curvature flow, and the grim reaper is not a blow-up solution. This proof is based on the curvature pinching of Huisken and Sinestrari [14,15].

Acknowledgement. The author would like to thank Gerhard Huisken for bringing the problem to his attention. He also wishes to thank his colleagues Ben Andrews for helpful discussions, Neil Trudinger for pointing out Proposition 3.1 to him, and in particular John Urbas for discussions on the proof of Theorem 5.2.

2. Level set estimates and proof of Theorem 1.3

In this section we prove estimate (1.5) and Theorem 1.3. Our proof of (1.5) involves elementary, but delicate analysis. To illustrate our idea, we first prove it in the dimension two case, then prove it for higher dimensions. For clarity we divide this section into 3 subsections. In §2.1 we prove (1.5) for $n = 2$. In §2.2 we prove (1.5) for $n > 2$. In §2.3 we prove Theorem 1.3.

Let $u$ be a complete convex solution of (1.2). For any constant $h > 0$ we denote

\begin{align}
\Gamma_h &= \Gamma_{h,u} = \{ x \in \mathbb{R}^n : u(x) = h \}, \\
\Omega_h &= \Omega_{h,u} = \{ x \in \mathbb{R}^n : u(x) < h \}.
\end{align}

Then $\Omega_h \subset \Omega_{h+\varepsilon}$ for any $\varepsilon > 0$. Let $\kappa$ denote the mean curvature of the level set $\Gamma_h$. We have

\begin{align}
\mathcal{L}_\sigma[u] &= \kappa u_\gamma + \frac{\sigma u_{\gamma\gamma}}{\sigma + u_\gamma^2} \\
&\geq \kappa u_\gamma = \mathcal{L}_0[u],
\end{align}

where $\gamma$ is the unit outward normal to $\Omega_{h,u}$, and $u_{\gamma\gamma} = \gamma_i \gamma_j u_{ij}$.

We may assume that $\Omega_h$ does not contain a straight line. For if $\Omega_{h_0}$ contains a straight line, then for all $h \geq h_0$, by convexity we have the splitting $\Omega_h = \Omega'_h \times \mathbb{R}^1$ for some convex set $\Omega'_h \subset \mathbb{R}^{n-1}$. The convexity implies that $u$ is a function of $x_1, \cdots, x_{n-1}$ if the straight line is parallel to the $x_n$-axis. Therefore the problem reduces to a lower dimension case. Furthermore, the graph of $u$, $\mathcal{M}_u$, does not contain any line segment. For it it does, the analyticity of $u$ when $\sigma > 0$, or the constant ranking of $(D^2u)$ when $\sigma = 0$ [14,15], implies that $\mathcal{M}_u$ contains a straight line.

We also remark that our proof of (1.5) works for general convex solutions of (1.2). When $\sigma = 0$ and the solution is a limit flow (blow-up solution) to a mean convex flow, one may
also use the noncollapsing result in [27, 28, 30] to give an alternative proof, see Remark 2.1 below.

2.1. Proof of (1.5) for n=2. Let $u$ be a complete convex solution of (1.2) satisfying $u(0) = 0$. We first prove that if $\Omega_1 \cap \{x_1 = 0\}$ is contained in $\{|x_2| \leq \beta\}$ for some small $\beta > 0$, then $\Omega_h$ is contained in a strip region for any $h > 0$. We prove the result in three lemmas. In the first one we assume that $\sigma = 0$ and $u$ is symmetric in $x_2$. In the second one we remove the symmetry assumption. In the third one we remove the condition $\sigma = 0$.

Lemma 2.1. Let $u$ be a complete convex solution of (1.2). Suppose $n = 2$, $\sigma = 0$, $u(0) = 0$, and $u$ is symmetric in $x_2$, namely $u(x_1, x_2) = u(x_1, -x_2)$. Suppose there is a sufficiently small $\beta > 0$ such that $u(0, \beta) \geq 1$. Then $u$ is defined in a strip region $\{|x_2| < C\}$.

Proof. Let $\mathcal{M}_u^+$ denote the graph of $u$ in the half-space $\{x_2 \geq 0\}$, and $D$ the projection of $\mathcal{M}_u^+$ on the plane $\{x_2 = 0\}$. Then $\mathcal{M}_u^+$ can be represented as the graph of a function $g$ in the form $\mathcal{M}_u^+ = \{(x_1, x_2, x_3) : x_2 = g(x_1, x_3)\}$, and $g$ is positive, concave, monotone increasing in $x_3$, defined in $D$, and vanishes on $\partial D$. In the following we also regard the height parameter $h$ as a variable and use $h$ instead of $x_3$.

For any $h > 0$, we denote $g_h(x_1) = g(x_1, h)$ and $D_h = \{x_1 : (x_1, h) \in D\}$. So $g_h$ is a positive, concave function of one variable, and $D_h$ is an interval in $\mathbb{R}^1$ containing the origin, $D_h = (-a_h, b_h)$ (here $a_h$ or $b_h$ might be equal to infinity). Denote $\bar{g}_h = g_h(0)$.

Claim 1: For any given $h > 0$, if $\bar{a}_h, a_h \geq \bar{b}_h$, then $\bar{a}_h \bar{b}_h \geq \frac{\pi}{\sqrt{2}} h$.

To prove the claim, we assume $\bar{a}_h \leq a_h$, otherwise we make the change $x_1 \to -x_1$. Denote $U_h = \Omega_h \cap \{x_1 > 0\}$. When $\sigma = 0$, the level set $\Gamma_h$ is evolving at the velocity equal to its curvature (with time $t = -h$). By the convexity of $U_h$ and the assumption $\bar{a}_h, a_h \geq \bar{b}_h$, we have $\bar{\alpha}_s, a_s \geq \frac{1}{2} \bar{b}_s$ for all $s \in (\frac{1}{2}h, h)$. Hence by the concavity of $g$ we have the gradient estimate $|\frac{d}{ds}g_s(0)| \leq 2$ for $s \in (\frac{1}{2}h, h)$. Note that $|\frac{d}{ds}|U_s|_{H^2}|$ is equal to the arc-length of the set of the unit normals to $\Gamma_s \cap \{x_1 > 0\}$. Hence $|\frac{d}{ds}|U_s|_{H^2}| \geq \frac{\pi}{4}$ for $s \in (\frac{1}{2}h, h)$, which implies $|U_h|_{H^2} \geq \frac{\pi}{4} h$. Here and below we use $|E|_{H^k}$ to denote the $k$-dim Hausdorff measure of the set $E$. By the convexity of $\Omega_h$ and the assumption $a_h \geq \bar{a}_h$, one sees that $U_h$ is contained in $(0, \bar{a}_h) \times (-2\bar{b}_h, 2\bar{b}_h)$. Hence $\bar{a}_h \bar{b}_h \geq \frac{1}{4}|U_h|_{H^2}$. We obtain $\bar{a}_h \bar{b}_h \geq \frac{\pi}{\sqrt{2}} h$.

Claim 1 is also true when $\sigma > 0$. Indeed, by equation (2.2) and the convexity we have $L_0[u] \leq 1$, which means $\Gamma_h$ is moving at a velocity greater than or equal to its curvature. Therefore we also have $|\frac{d}{ds}|U_s|_{H^2}| \geq \frac{\pi}{4}$ for $s \in (\frac{1}{2}h, h)$, and so it also follows $\bar{a}_h \bar{b}_h \geq \frac{\pi}{\sqrt{2}} h$.

In particular, the proof implies Claim 1 holds for convex functions $u$ satisfying $L_0[u] \leq C_1$ for some positive constant $C_1$. That is if $L_0[u] \leq C_1$, then $\bar{a}_h \bar{b}_h \geq C_2 h$, where $C_2$ depends on $C_1$.

Claim 2: Denote $h_k = 2^k$, $\bar{a}_k = \bar{a}_h$, $\bar{b}_k = \bar{b}_h$, $g_k = g_{h_k}$, and $D_k = D_{h_k}$. Then

\[ g_k(0) \leq g_{k-1}(0) + \frac{2^{-k/8}}{7} \] for all $k \geq 1$. 

Note that Lemma 2.1 follows from Claim 2 immediately. Indeed, let \( \Omega_\infty = \bigcup_{h > 0} \Omega_h \) be the domain of definition of \( u \). By (2.3), \( \bar{\nabla}_k \) is uniformly bounded. Hence by Claim 1, \( \Omega_\infty \) is a convex set containing the whole \( x_1 \)-axis. Hence \( \Omega_\infty = I \times \mathbb{R}^1 \) for some interval \( I \) in the \( x_2 \) axis. Estimate (2.3) implies that \( I \subset (-2, 2) \) (see (2.5) below). Hence \( \Omega_\infty \) must be a strip region.

To prove (2.3) we observe that, since \( g \) is positive and concave, \( g_k(0) \leq h_k g_0(0) \leq 2^k \beta \). Hence we may assume that \( g_{k_0}(0) \leq 1 \) for some sufficiently large \( k_0 \). By Claim 1, we have

\[
\bar{a}_k \geq C_0 h_k
\]

for \( k \leq k_0 \) with \( C_0 = \frac{\pi}{32} \). We prove (2.3) by induction, starting at \( k = k_0 \).

Suppose by induction that (2.3) holds up to \( k \). Then by induction,

\[
g_k(0) \leq g_{k_0}(0) + \sum_{j=k_0}^{k} 2^{-j/8} \leq 2.
\]

By the concavity of \( g \) and since \( g \geq 0 \), we have \( g_{k+1}(0) \leq 2g_k(0) \leq 4 \). By Claim 1, \( \bar{a}_{k+1} \geq \frac{\pi}{128} h_k \). Hence (2.4) holds at \( k + 1 \) with \( C_0 = \frac{\pi}{128} \).

To prove (2.3) at \( k + 1 \), denote

\[
L_k = \{ x_1 \in \mathbb{R}^1 : -\frac{C_0}{4} h_k < x_1 < \frac{C_0}{4} h_k \},
\]

\[
Q_k = L_k \times [h_k, h_{k+1}] \subset D,
\]

where \( C_0 \) is given in (2.4). Since \( g > 0 \), \( g \) is concave, and \( g(x_1, h) \) is defined in \( 2L_k \) for \( h \geq \frac{1}{2} h_k \), we have

\[
\sup\{g(x_1, h) : (x_1, h) \in Q_k\} \leq 2 \sup\{g(x_1, h_k) : x_1 \in L_k\} \\
\leq 4g(0, h_k) = 4g_k(0) \leq 8.
\]

Moreover, for any \( (x_1, h) \in Q_k \),

\[
|\partial_h g(x_1, h)| \leq \frac{g(x_1, h) - g(x_1, h_{k-1})}{h - h_{k-1}} < \frac{g(x_1, h)}{h_k - h_{k-1}} \leq \frac{16}{h_k}.
\]

Similarly,

\[
|\partial_{x_1} g(x_1, h)| \leq \frac{g(x_1, h)}{a_h} \frac{2g(x_1, h)}{h_k} \leq \frac{16}{h_k} \quad \forall \ (x_1, h) \in Q_k.
\]

From the above gradient estimates and the concavity of \( g \), the average in \( Q_k \) of the second derivative satisfies

\[
(*) \quad |\partial_{x_1}^2 g(x_1, h)| \approx \sup_{x_1 \in L_k} |\partial_{x_1} g(x_1, h)| |L_k|_{H^1} \approx h^{-2}.
\]
Here \( a \approx b \) means \( a \leq Cb \) and \( b \leq Ca \) for some constant \( C \). This simple observation is critical for the proof of (2.3), and actually the following weaker version is sufficient,

\[
|\partial^2_{x_1} g(x_1, h)| \leq Ch^{-5/4}_k \quad (x_1, h) \in Q_k
\]

for some fixed constant \( C \). Indeed, by equation (2.2), we have \( ku_\gamma = 1 \) (when \( \sigma = 0 \)). Note that \( u_\gamma \approx (\partial_h g)^{-1} \) and \( \kappa \approx \partial_{x_1 x_1} g \) when \( (x_1, h) \in Q_k \). Hence if (2.9) holds, we have

\[
|\partial_h g(0, h)| \leq Ch^{-5/4}_k \quad \text{for } h \in (h_k, h_{k+1}).
\]

It follows that

\[
g_{h_{k+1}}(0) - g_{h_k}(0) = g(0, h_{k+1}) - g(0, h_k) \leq Ch^{-1/4}_k \leq h^{-1/8}_k
\]

when \( k \) is large. We obtain (2.3).

However we have not proved the estimate (2.9) pointwise, even in the special case \( \sigma = 0 \). But we observe that the set where \( g \) does not satisfies (2.9) is very small, and the concavity of \( g \) ensures that this small set does not harm the estimate (2.3).

Denote

\[
\chi = \{(x_1, h) \in Q_k : |\partial^2_{x_1} g(x_1, h)| \geq h^{-5/4}_k\}.
\]

If \( \chi \) is empty, (2.3) is proved in (2.11) above. If \( \chi \neq \emptyset \), we proceed as follows (the argument also applies to the case \( \chi \) is empty). For any \( h \in (h_k, h_{k+1}) \), by the gradient estimates and the concavity of \( g \), an integration by parts gives

\[
|\{x_1 \in L_k : (x_1, h) \in \chi\}|_{H^1,k}h^{-5/4}_k \leq \left| \int_{L_k} \partial_{x_1 x_1} g \right| \leq 2 \sup_{L_k} |\partial_{x_1} g| \leq Ch^{-1}_k.
\]

Taking integration from \( h = h_k \) to \( h = h_{k+1} \) we obtain \( |\chi|_{H^2,k}h^{-5/4}_k \leq C \), namely

\[
|\chi|_{H^2,k} \leq C h^{5/4}_k.
\]

We say \( \chi \) is a small set as the ratio \( |\chi|_{H^2,k}/|Q_k|_{H^2} = O(h^{-3/4}_k) \) is small.

For any given \( y_1 \in L_k \) we denote \( \chi_{y_1} = \chi \cap \{x_1 = y_1\} \). From (2.12) and by the Fubini Theorem, there is a set \( \tilde{L} \subset L_k \) with measure \( |	ilde{L}|_{H^1} < h^{1/2}_k \) such that for any \( y_1 \in L_k - \tilde{L} \),

\[
|\chi_{y_1}|_{H^1} \leq C h^{3/4}_k.
\]

For any \( y_1 \in L_k - \tilde{L} \), we have

\[
g(y_1, h_{k+1}) - g(y_1, h_k) = \int_{\chi_{y_1}} \partial_h g(y_1, h) dh + \left( \int_{h_k}^{h_{k+1}} - \int_{\chi_{y_1}} \right) \partial_h g(y_1, h) dh.
\]
By (2.13) and the gradient estimate (2.7), the first integral is bounded by 
\[ C h_k^{-1/4}. \]
For the second one, similarly as in (2.10) we have 
\[ \partial \cdot g \leq C h_k^{-5/4} \]
for any point \((x, h) \notin \chi\). Hence the second integral is also bounded by 
\[ C h_k^{-1/4}. \]
Therefore we obtain
(2.15)
\[ g(y_1, h_{k+1}) - g(y_1, h_k) \leq C h_k^{-1/4}. \]

From (2.15) we get (2.3) immediately. Indeed, replacing \(x_1\) by 
\(-x_1\) if necessary, we assume that 
\[ \partial x_1 g(0, h_k) \leq 0, \]
so that \(g(x_1, h_k) \leq g(0, h_k)\) for all \(x_1 \geq 0\). Since \(|\tilde{L}| < h_k^{1/2}\), 
the set \([0, h_k^{1/2}] - \tilde{L}\) is not empty. Let \(y_1 \in [0, h_k^{1/2}] - \tilde{L}\). By (2.15) we obtain
(2.16)
\[ g(y_1, h_{k+1}) \leq g(y_1, h_k) + C h_k^{-1/4} \leq g(0, h_k) + C h_k^{-1/4}. \]

Note that \(g\) is positive and concave, and that \(g\) is defined on the interval 
\([0, \alpha_{k+1}]\) with \(\alpha_{k+1} \geq Ch_k + 1\) \((C = \pi/128\) as established before). We have
\[ \frac{g_{k+1}(0)}{g_{k+1}(y_1)} \leq \frac{\alpha_{k+1}}{\alpha_{k+1} - |y_1|} = 1 + Ch_k^{-1/2} \]
By (2.16) it follows (recall our notation, \(g(y_1, h_{k+1}) = g_{k+1}(y_1)\)),
\[ g_{k+1}(0) \leq g_k(0) + Ch_k^{-1/4}. \]

We obtain (2.3). Lemma 2.1 is proved. \(\square\)

In Lemma 2.1, we don’t need to assume that the sub-level set \(\Omega_h\) is compact, nor we assume the whole sub-level set \(\Omega_h|_{h=1}\) is contained in a strip region. The assumption that \(u(0, \beta) \geq 1\) for sufficiently small \(\beta > 0\) implies that \(\Omega_1 \cap \{x_1 > 0\}\) if \(u_{x_1}(0, \beta) > 0\), or \(\Omega_1 \cap \{x_1 < 0\}\) if \(u_{x_1}(0, \beta) < 0\), is contained in a strip \(\{x_2 | \leq \beta\}\). Next we remove the assumption that \(u\) is symmetric in \(x_2\).

**Lemma 2.2.** Let \(u\) be a complete convex solution of (1.2). Suppose \(n = 2, \sigma = 0, u(0) = 0\), 
and there is a sufficiently small \(\beta > 0\) such that \(u(0, \beta) \geq 1\) and \(u(0, -\beta) \geq 1\). Then \(u\) is defined in a strip region.

Note that the assumption \(u(0, \beta) \geq 1\) and \(u(0, -\beta) \geq 1\) is equivalent to that \(\Omega_1 \cap \{x_1 = 0\} \subset \{|x_2| < \beta\}\). Before proving Lemma 2.2, we state a property of convex domain, due to F. John [21], which is frequently used in the study of convex bodies and Monge-Ampère equations.

**Proposition 2.1.** Let \(\Omega\) be a bounded, convex domain in \(\mathbb{R}^n\), \(n \geq 2\). Then among all 
(solid) ellipsoids containing \(\Omega\), there is a unique ellipsoid \(E\) of smallest volume such that
(2.17)
\[ \frac{1}{n} E \subset \Omega \subset E, \]
where $\alpha E$ is the $\alpha$-dilation of $E$ with respect to its center.

We call $E$ the minimum ellipsoid of $\Omega$ (it is a (solid) ellipse when $n = 2$). By a rotation of the coordinates, we may assume that $E$ is given by $E = \{\sum_{i=1}^{n} (\frac{x_i - x_{0,i}}{r_i})^2 < 1\}$, where $x_0 = (x_{0,1}, \cdots, x_{0,n})$ is the center of $E$. We can make the linear transform $y_i = (x_i - x_{0,i})/r_i + x_{0,i}$, $i = 1, \cdots, n$, such that $E$ becomes the unit ball $B_1(x_0)$ and $B_{1/n}(x_0) \subset T(\Omega) \subset B_1(x_0)$.

Proof of Lemma 2.2. Let $R = 10^3$ and let $E$ be the minimum ellipsoid of $\Omega \cap B_R(0)$. By a rotation of coordinates we assume the axial directions of $E$ have a rotation of coordinates we assume the axial directions of $E$ coincide with those of the coordinate system (we don’t need to assume the center of $E$ is at the origin).

The proof is similar to that of Lemma 2.1. We indicate the necessary changes. Let $\mathcal{M}_u$ be the graph of $u$, which consists of two parts, $\mathcal{M}_u = \mathcal{M}^+ \cup \mathcal{M}^-$, where $\mathcal{M}^+ = \{(x, u(x)) \in \mathbb{R}^3 : \partial_{x_2} u(x) \geq 0\}$ and $\mathcal{M}^- = \{(x, u(x)) \in \mathbb{R}^3 : \partial_{x_2} u(x) \leq 0\}$. Then $\mathcal{M}^\pm$ can be represented as graphs of functions $g^\pm$ in the form $x_2 = g^\pm(x_1, 3)$, $(x_1, 3) \in D$ and $D$ is the projection of $\mathcal{M}_u$ on the plane $\{x_2 = 0\}$. The functions $g^+$ and $g^-$ are respectively concave and convex, and we have $x_3 = u(x_1, g^\pm(x_1, 3))$. Denote

$$g = g^+ - g^-.$$

Then $g$ is a positive, concave function in $D$, vanishing on $\partial D$. For any $h > 0$ we also denote $g_h(x_1) = g(x_1, h)$, $g^\pm_h(x_1) = g^\pm(x_1, h)$, and $D_h = \{x_1 \in \mathbb{R}^1 : (x_1, h) \in D\}$. Then $g_h$ is a positive, concave function in $D_h$, vanishing on $\partial D_h$, and $D_h = (-\overline{a}_h, \overline{a}_h)$ is an interval containing the origin. As before we denote $\overline{b}_h = g_h(0)$.

Claim 1: Suppose $\overline{a}_h, \underline{a}_h \geq \overline{b}_h$. Then $\overline{a}_h \overline{b}_h \geq \frac{\pi}{32} h$.

The claim can be proved in the same way as in Lemma 2.1, by observing that the gradient estimate $|\frac{d}{dx_1} g_s(0)| \leq 2$ also implies that the arc-length of the set of the unit normals to $\Gamma_s \cap \{x_1 > 0\}$ is greater than $\frac{\pi}{4}$. Hence we also have $\frac{d}{ds} |U_s|_{H^2} \geq \frac{\pi}{4}$ for $s \in \left(\frac{1}{3} h, h\right)$.

Claim 2: Denote $h_k = 2^k$, $\overline{a}_k = \overline{a}_{h_k}$, $\overline{b}_k = \overline{b}_{h_k}$, $g_k = g_{h_k}$, and $D_k = D_{h_k}$. We have

$$g_k(0) \leq g_{k-1}(0) + 2^{-k/8} \quad \text{for all } k \geq 1.$$

Lemma 2.2 follows from Claim 2 immediately. Indeed, let $P$ be the projection of the graph $\mathcal{M}_g$ on the plane $\{x_3 = 0\}$. Then $P$ is convex set containing the $x_1$-axis. Hence $P = I \times \mathbb{R}^1$ for some interval $I$. Estimate (2.19) implies that $g(0, h) \leq 2$ for all $h$ (due to (2.5)), so we have $I \subset [0, 2]$. Hence $\mathcal{M}_g$ is contained in the strip $\{(x_1, x_2, x_3) \in \mathbb{R}^3 : 0 \leq x_2 \leq 2\}$. By (2.18), $\mathcal{M}_u$ is also contained in a strip region $\{\{a_1 x_1 + a_2 x_2 < 2\}$, where $(a_1, a_2, 0)$ is a unit vector in $\mathbb{R}^3$ with $a_1$ small and $a_2$ close to 1. We can make $a_1$ as small as we want, provided the constant $R$ at the beginning of the proof is sufficiently large.

The proof of (2.19) is similar to that of (2.3). But the argument from (2.9) to (2.10) needs to use the equation (2.2). Therefore we need to consider $g^+$ and $g^-$ instead of $g$. 

11
First we establish (2.4)-(2.8) in the same way as in Lemma 2.1. Let $L_k, Q_k$ and $\chi$ be as in Lemma 2.1. We also denote

$$\chi^\pm = \{(x_1, h) \in Q_k : |\partial^2_{x_1}g^\pm(x_1, h)| \geq h_k^{5/4}\}.$$  

Then both $\chi^+$ and $\chi^-$ are subsets of $\chi$. For any $h \in (h_k, h_{k+1})$, by (2.8) and recalling that $L_k = (-\frac{1}{4}C_0h_k, \frac{1}{4}C_0h_k)$, we have

$$\left|\{x_1 \in L_k : (x_1, h) \in \chi^+\}\right| \leq \int_{L_k} \partial_{x_1}g^+ \, dh,$$

where the second inequality is due to that $g = g^+ - g^-$, $g^+$ is concave and $g^-$ is convex. Hence $|\chi^+|_{\mathcal{H}^2} \leq Ch_k^{5/4}$. Similarly we have $|\chi^-|_{\mathcal{H}^2} \leq Ch_k^{5/4}$.

For any given $y_1 \in L_k$, denote $\chi^{\pm}_{y_1} = \chi^\pm \cap \{x_1 = y_1\}$. Then there is a set $\tilde{L}^\pm \subset L_k$ with measure $|\tilde{L}^\pm|_{\mathcal{H}^1} < h_k^{1/2}$ such that for any $y_1 \in L_k - \tilde{L}^\pm$, we have $|\chi^{\pm}_{y_1}|_{\mathcal{H}^1} \leq Ch_k^{3/4}$.

For any given $y_1 \in L_k - (\tilde{L}^+ \cup \tilde{L}^-)$, we have

$$g(y_1, h_{k+1}) - g(y_1, h_k) = g^+(y_1, h_{k+1}) - g^+(y_1, h_k) + |g^-(y_1, h_{k+1}) - g^-(y_1, h_k)|.$$  

In the following we estimate $g^+(y_1, h_{k+1}) - g^+(y_1, h_k)$. The estimate also applies to $|g^-(y_1, h_{k+1}) - g^-(y_1, h_k)|$. We have

$$g^+(y_1, h_{k+1}) - g^+(y_1, h_k) = \int_{h_k}^{h_{k+1}} \partial_h g^+(y_1, h) \, dh$$

$$= \int_{\chi^{\pm}_{y_1}} \partial_h g^+(y_1, h) \, dh + \left( \int_{h_k}^{h_{k+1}} - \int_{\chi^{\pm}_{y_1}} \right) \partial_h g^+(y_1, h) \, dh.$$  

For the first integral on the right hand side, note that $g = g^+ - g^-$, $g^+(y_1, h)$ is concave and increasing in $h$, and $g^-$ is convex and decreasing in $h$. Hence $\partial_h g^+ \leq \partial_h g$. By the gradient estimate (2.7) and recalling that $|\chi^{\pm}_{y_1}|_{\mathcal{H}^1} \leq Ch_k^{3/4}$, we have

$$\int_{\chi^{\pm}_{y_1}} \partial_h g^+(y_1, h) \, dh \leq Ch_k^{-1/4}.$$  

To estimate the second integration, we first introduce a mapping $T : p \to q$ as follows. For a point $p = (x_1, h) \in D$, there is a corresponding point $P = (x_1, x_2, h)$ on the level set $\Gamma_h$, where $x_2 = g^+(x_1, h)$, such that $p$ is the projection of $P$ on the plane $\{x_2 = 0\}$. Let $q = (x_1, x_2)$ be the projection of $P$ on the plane $\{x_3 = 0\}$.
By equation (2.2), we have $\kappa u_\gamma = 1$. Note that when $p = (x_1, h) \in Q_k$, the normal $\gamma$ of the level set $\Gamma_h \subset \mathbb{R}^2$ at the point $q = T(p) \in \Gamma_h$ satisfies

\begin{equation}
|\gamma - e_2| < \varepsilon
\end{equation}

for some small constant $\varepsilon > 0$, where $e_2 = (0, 1)$. This is because by induction, $\Omega_{h_k} \cap B_R$ is contained in a strip region (see discussion after (2.19)) and the axial directions of the minimum ellipsoid of $\Omega_{h_k} \cap B_R$ is a small perturbation of the axial directions of the coordinates, where $R$ is the constant introduced at the beginning of the proof. Therefore we have

\begin{equation}
\begin{cases}
(\partial_h g^+)^{-1} = (1 + \varepsilon_1)u_\gamma, \\
\partial_{x_1x_1}g^+ = (1 + \varepsilon_2)\kappa,
\end{cases}
\end{equation}

where $\varepsilon_1, \varepsilon_2$ are small constants provided $R$ is sufficiently large. Hence

\begin{equation}
|\partial_h g^+(y_1, h)| \leq C|\partial_{x_1x_1}g^+| \leq Ch_k^{-5/4} \quad \forall (y_1, h) \notin \chi^+.
\end{equation}

It follows that

\[
\left( \int_{h_k}^{h_{k+1}} - \int_{x_1^+} \right) \partial_h g^+(y_1, h) dh \leq Ch_k^{-1/4}.
\]

Combining the above two estimates we obtain

\[g^+(y_1, h_{k+1}) - g^+(y_1, h_k) \leq Ch_k^{-1/4}.
\]

Similarly we have $|g^-(y_1, h_{k+1}) - g^-(y_1, h_k)| \leq Ch_k^{-1/4}$. Therefore we obtain (2.19) just as we prove (2.3) from (2.15).

Next we remove the condition $\sigma = 0$ in Lemma 2.2.

**Lemma 2.3.** Let $u$ be a complete convex solution of (1.2). Suppose $n = 2$, $u(0) = 0$, and there is a sufficiently small $\beta > 0$ such that $u(0, \beta) \geq 1$ and $u(0, -\beta) \geq 1$. Then $u$ is defined in a strip region.

**Proof.** We can follow the proof of Lemma 2.2 until (2.20) without any change. The estimate for the second integral on the right hand side of (2.20) used the equation $\kappa u_\gamma = 1$. But when $\sigma \neq 0$, equation (2.2) contains an extra term $\frac{\sigma u_\gamma^2}{\sigma + u_\gamma^2}$. To handle this extra term, we need to divide the integral (2.20) into three parts,

\begin{equation}
g^+(y_1, h_{k+1}) - g^+(y_1, h_k) = \int_I \partial_h g^+(y_1, h) dh
\end{equation}

\[
= \left( \int_{I_1} + \int_{I_2} + \int_{I_3} \right) \partial_h g^+(y_1, h) dh.
\]
where \( I = (h_k, h_{k+1}) \),
\[
I_1 = \chi_{y_1}^+,
\]
\[
I_2 = \{ h \in I - I_1 : \frac{\sigma u_{\gamma\gamma}(q)}{\sigma + u_{\gamma}^2(q)} \leq \frac{1}{2} \},
\]
\[
I_3 = I - (I_1 \cup I_2),
\]
where \( q = \mathcal{T}(p), p = (y_1, h) \), and \( \mathcal{T} \) is the mapping introduced after (2.20).

Similarly as in Lemma 2.2, we have \( \partial_h g^+ \leq \partial_h g \leq C/h \) for \( h \in (h_k, h_{k+1}) \) and the first integral \( \int_{I_1} \partial_h g^+(y_1, h) dh \leq C h_k^{-1/4} \).

For the second one, noting that when \( \frac{\sigma u_{\gamma\gamma}}{\sigma + u_{\gamma}^2} < \frac{1}{2} \), we have, by (2.22),
\[
(\partial_h g^+)^{-1} \partial_{x_1 x_1} g^+ \approx \kappa u_{\gamma} \geq \frac{1}{2}.
\]
Hence \( \partial_h g^+ \leq C \partial_{x_1 x_1} g^+ \) and we obtain \( \int_{I_2} \partial_h g^+(y_1, h) dh \leq C h_k^{-1/4} \).

To estimate the third integral in (2.24), note that for any point \( p = (y_1, h) \) with \( h \in I_3 \), we have
\[
(2.25)
\]
\[
\begin{align*}
&u_{\gamma}(q) = u_{x_1}(q)(1 + \varepsilon_1), \\
&u_{\gamma\gamma}(q) = u_{x_2 x_2}(q)(1 + \varepsilon_2) + o(u_{x_2})
\end{align*}
\]
at the point \( q = \mathcal{T}(p) \), for some small constants \( \varepsilon_1 \) and \( \varepsilon_2 \). The first formula is due to (2.21). To verify the second one in (2.25), one chooses a coordinate system \( (z_1, z_2) \) such that \( q \) is the origin, \( \gamma \) is in the \( z_2 \)-axis and \( \Gamma_h \) is locally given by \( z_2 = \eta(z_1) \). One then differentiates \( u(z_1, \eta(z_1)) = h \) twice to obtain \( u_{z_1 z_1} + u_{z_2} \kappa = 0 \). Recall that when \( p = (y_1, h) \) with \( h \in I_3, \kappa \leq C h_k^{-5/4} \). Hence \( u_{z_1 z_1} = o(u_{z_2}) \), from which one easily obtains (2.25).

Since for any \( p \in \{ y_1 \} \times I_3, \frac{\sigma u_{\gamma\gamma}(q)}{\sigma + u_{\gamma}^2(q)} \geq \frac{1}{3} \). Therefore by (2.25) we have
\[
\frac{\sigma u_{x_2 x_2}(q)}{\sigma + u_{x_2}^2(q)} \geq \frac{1}{3}.
\]
Notice that \( 0 \leq \sigma \leq 1 \). Hence
\[
(2.26)
\]
\[
\quad u_{x_2 x_2} \geq \frac{1}{4}(\sigma + u_{x_2}^2) \geq \frac{1}{4} u_{x_2}^2.
\]

Now by the relation \( h = u(y_1, x_2) \) and \( x_2 = g^+(y_1, h) \), we have \( h = u(y_1, g^+(y_1, h)) \). As \( y_1 \) is fixed, we can regard \( u \) and \( g^+ \) as functions of one variable. Differentiating in \( h \) gives \( 1 = u'(g^+) \), differentiating twice we get \( 0 = u''(g^+)^2 + u'(g^+)^\prime \). Hence
\[
(g^+)^\prime\prime = -\frac{u''}{u'}(g^+)^2 = -u''(g^+)^3.
\]
By (2.26) we then obtain

$$(2.27) \quad (g^+)' \leq -\varphi(h)(g^+)'$$

where $\varphi(h) = \frac{1}{4}$ if $h \in I_3$ and $\varphi(h) = 0$ otherwise. Observing that $(g^+)' > 0$, we obtain

$$
\int_{h_k}^{h} (g^+)' \leq - \int_{h_k}^{h} \varphi = -\frac{1}{4}|I_{3,h}| \quad \forall h \in (h_k, h_{k+1}),
$$

namely

$$ \log((g^+)'(h)) \leq \log((g^+)'(h_k)) - \frac{1}{4}|I_{3,h}|,$$

or equivalently

$$(2.28) \quad (g^+)'(h) \leq (g^+)'(h_k)e^{-|I_{3,h}|/4},$$

where $I_{3,h} = I_3 \cap [h_k, h]$. Since $I_3 = \bigcup_k (a_k, b_k)$ is the union of intervals, and $g^+$ is increasing, the third integral in (2.24) is equal to $\text{osc}_{I_3} g^+ = \sum_k g^+(b_k) - g^+(a_k)$. We have

$$(2.29) \quad \text{osc}_{I_3} g^+ \leq (g^+)'(h_k) \int_{I_3} e^{-|I_{3,h}|/4}$$

$$
\leq (g^+)'(h_k) \int_{h_k}^{h_{k+1}} e^{-(h-h_k)/4}$$

$$\leq 2(g^+)'(h_k) \leq \frac{C}{h_k}.
$$

This completes the proof. \qed

Next we prove an auxiliary lemma.

**Lemma 2.4.** Let $u$ be a complete convex solution of (1.2). Suppose $n = 2$, $u(0) = 0$, $\delta := \inf \{|x| : x \in \Gamma_1\}$ is attained at $x_0 = (0, -\delta) \in \Gamma_1$, and $\delta > 0$ is sufficiently small. Then $D_1$ contains the interval $(-R, R)$ with

$$(2.30) \quad R \geq (-\log \delta - C)^{1/2},$$

where $C > 0$ is independent of $\delta$, $D_h$ is the set introduced in the proof of Lemma 2.2.

**Proof.** Suppose near $x_0$, $\Gamma_1$ is given by

$$x_2 = g(x_1).$$

Then $g$ is a convex function, $g(0) = -\delta$, and $g'(0) = 0$. Let $a, b > 0$ be two constants such that $g(a) = 0$ and $g'(b) = 1$. To prove (2.30) it suffices to prove

$$(2.31) \quad b \geq (-\log \delta - C)^{1/2}.$$
For any \( y = (y_1, y_2) \in \Gamma_1 \), where \( y_1 \in [0, b] \), let \( \xi = y/|y| \). By the convexity of \( u \),
\[
  u_\xi(y) \geq \frac{u(y) - u(0)}{|y|} = \frac{1}{|y|}.
\]
Let \( \theta \) denote the angle between \( \xi \) and the tangential vector \( \frac{1}{\sqrt{1+g'^2}} (1, g') \) of \( \Gamma_1 \) at \( y \). Then
\[
  \cos \theta = \frac{\xi_1 + \xi_2 g'(y_1)}{\sqrt{1+g'^2}} ,
\]
\[
  \sin \theta = \sqrt{1 - \cos^2 \theta} = \frac{\xi_1 g' - \xi_2}{\sqrt{1+g'^2}} .
\]
Hence
\[
  u_\gamma(y) = u_\xi(y)/\sin \theta \geq \frac{\sqrt{1+g'^2}}{y_1 g' - y_2},
\]
where \( \gamma \) is the normal of the sub-level set \( \Omega_1 = \{u < 1\} \). By \( L_0[u] \leq 1 \), we obtain,
\[
  \frac{g''}{(1+g'^2)^{3/2}} \frac{\sqrt{1+g'^2}}{y_1 g' - y_2} \leq \kappa u_\gamma(y) \leq 1,
\]
where \( \kappa \) is the curvature of the level set \( \Gamma_1 = \{u = 1\} \). Hence
\[(2.32)\]
\[
  g''(y_1) \leq (1+g'^2)(y_1 g' - y_2) \leq \begin{cases} 
  2(y_1 g' + \delta) & \text{if } y_2 \leq 0, \\
  2y_1 g' & \text{if } y_2 \geq 0,
\end{cases}
\]
where \( y_2 = g(y_1) \) and \( g'(y_1) \leq 1 \) for \( y_1 \in (0, b) \). We consider the equation
\[
  \rho''(t) = \begin{cases} 
  2(t \rho'(t) + \delta) & \text{if } \rho(t) \leq 0 \\
  2t \rho'(t) & \text{if } \rho(t) \geq 0
\end{cases}
\]
with the initial condition \( \rho(0) = -\delta \) and \( \rho'(0) = 0 \). Let \( \alpha > 0 \) such that \( \rho(\alpha) = 0 \). Then for \( t \in (0, \alpha) \) we have
\[
  \rho'(t) = 2\delta e^{t^2} \int_0^t e^{-s^2} ds.
\]
Hence we have \( C_1 \leq \alpha \leq C_2 \) and \( \rho'(\alpha) \leq C_2 \delta \) for some constants \( C_1, C_2 \). Let \( \beta > \alpha \) such that \( \rho'(\beta) = 1 \). Consider the equation
\[
  \rho'' = 2t \rho'
\]
in the interval \((\alpha, \beta)\). Then
\[
  \log \rho' |_{\alpha}^\beta = t^2 |_{\alpha}^\beta
\]
We obtain
\[
  \beta^2 \geq |\log \delta| - C.
\]
By the comparison principle we have \( g \leq \rho \). Hence (2.31) holds. □
Theorem 2.1. Let $u$ be an entire convex solution of (1.2) in $\mathbb{R}^2$. Then
\begin{equation}
(2.33) \quad u(x) \leq C(1 + |x|^2),
\end{equation}
where the constant $C$ depends only on the upper bound for $u(0)$ and $|Du(0)|$.

Proof. By adding a constant to $u$ we may suppose $u(0) = 0$. To prove (2.33) it suffices to prove that $\text{dist}(0, \Gamma_h) \geq Ch^{1/2}$ for all large $h$. By the rescaling $u_h(x) = \frac{1}{h}u(h^{1/2}x)$ it suffices to prove $\text{dist}(0, \Gamma_{1,u_h}) \geq C$. Note that $|Du_h(0)| = h^{-1/2}|Du(0)| \leq |Du(0)|$. Hence by convexity, $\inf_{B_1(0)} u_h$ is uniformly bounded from below. Note also that $u_h$ satisfies equation (1.2) with $\sigma$.

Let $\delta = \inf\{|x| : x \in \Gamma_{1, u_h}\}$. Suppose the infimum is attained at $x_0 = (0, -\delta)$. If $\delta > 0$ is sufficiently small, by Lemma 2.4, $D_{1, u_h}$ contains the interval $(-R, R)$, where $R = (-log \delta - C)^{1/2}$. Let $\delta^* > 0$ such that $u_h(0, \delta^*) = 1$. Then $\delta^*$ must also be very small, for otherwise by convexity the ellipse

$$E = \{(x_1, x_2) \in \mathbb{R}^2 : \frac{x_1^2}{(R/4)^2} + \frac{|x_2 - (\delta^* - \delta)/2|^2}{[(\delta^* + \delta)/8]^2} < 1\}$$

is contained in sub-level set $\Omega_{1, u_h}$.

When $\sigma = 0$, the level set $\Gamma_{-t, u_h}$ is a solution to the curve shortening flow (for time $t$ starting at $-1$). Let $E_\sigma$ be the solution to the curve shortening flow with initial condition $E_{-1} = E$, where $E$ is the ellipse given above. Therefore we have the inclusion $E_{-t} \subset \Omega_{-t, u_h}$ for all $t > -1$. It takes the time $T = |E|_{\mathcal{H}^2}$ for the solution $E_{-t}$ to shrink to a point. Hence we have $\inf_{B_1(0)} u_h \leq 1 - T$. But when $\delta$ is small and $\delta^*$ has a positive lower bound (independent of $\delta$), $T = |E|_{\mathcal{H}^2}$ becomes sufficiently large, which contradicts with the assertion that $\inf_{B_1(0)} u_h$ is uniformly bounded from below.

When $\sigma \in (0, 1]$, $u_h$ is a solution of (1.2) with $\sigma \leq 1/h$. If there is a sequence $h_k \to \infty$ and $\delta_k^* \geq \delta^*$ for some $\delta^* > 0$ such that $u_{h_k}(0, \delta_k^*) = 1$, we define $E$ as above. Now let $v_\sigma$ be the solution of $\mathcal{L}_h(v) = 1$ in $E$ and $v = 1$ on $\partial E$. Then for any given $\delta, \delta^* > 0$ and $R > 1$, the solution $v_\sigma$ converges to $v_0$, the solution to $\mathcal{L}_0(v_0) = 1$ in $E$ and $v_0 = 1$ on $\partial E$. The level set of $v_0$ is a solution to the curve shortening flow. Hence $\inf v_\sigma \to -\infty$ as $\delta, \sigma \to 0$. We also reach a contradiction. \hfill \Box

Corollary 2.1. Let $u$ be a complete convex solution of (1.2). Then $u$ is either an entire solution, or is defined in a strip region. In particular, there is no complete convex solution of (1.2) defined in a half space.

Proof. Let us assume $u(0) = 0$. If $u$ is not an entire solution, then for any $M > 1$, there exists $x_0 \in \mathbb{R}^n$ such that $u(x_0) > M|x_0|^2$. Let $u_h(x) = h^{-1}u(h^{1/2}x)$, where $h = u(x_0)$. Then the distance from the origin to the level set $\Gamma_1 = \{u = 1\}$ is less than $M^{-1}$. The proof of Theorem 2.1 then implies that $u$ is defined in a strip region. \hfill \Box

Note that in the above proof we have used the following lemma.
**Lemma 2.5.** Let $u_k$ be a sequence of convex solutions of (1.2) with $\sigma = \sigma_k \in [0,1]$. Suppose $\sigma_k \rightarrow \sigma$ and $u_k \rightarrow u$. Then $u$ is a convex solution of (1.2).

**Proof.** Lemma 2.5 is well known if $\sigma_k \equiv 0$ or $\sigma_k \equiv 1$. If $\sigma_k \rightarrow \sigma > 0$, replacing $u_k$ by $\frac{1}{\sigma_k}u(\sqrt{\sigma_k}x)$ we may suppose $\sigma_k \equiv 1$. We need only to consider the case when $\sigma_k \rightarrow 0$.

In this case we show that $u$ is a viscosity solution of $\mathcal{L}_0[u] = 0$. Indeed, since $\mathcal{L}_{\sigma_k}[u_k] = 1$, by convexity we have $\mathcal{L}_0[u_k] \leq 1$ and so $\mathcal{L}_0[u] \leq 1$. On the other hand, for any fixed $\hat{\sigma} > 0$, by convexity we have $\mathcal{L}_\sigma[u_k] \geq \mathcal{L}_{\sigma_k}[u_k] = 1$ if $k$ is sufficiently large such that $\sigma_k < \hat{\sigma}$. Hence $\mathcal{L}_\sigma[u] \geq 1$. As $\hat{\sigma} > 0$ is arbitrary, we have $\mathcal{L}_0[u] \geq 1$. □

**Remark 2.1.** When $\sigma = 0$ and $u$ is a blow-up solution (limit flow) to a given mean convex flow, by a compactness argument, together with Lemma 2.4 and the proof of Theorem 2.1, one sees that (1.5) also follows from the non-collapse in [27,28,30]. That is if (1.5) is not true, there exists a sequence of blow-up solutions $u_k$ to a given mean convex flow such that $w_k(x) := k^{-1}u_k(k^{1/2}x)$ converges to a multiplicity two plane. But a multiplicity two plane does not occur as a blow-up solution [27, 28, 30].

**2.2. Proof of (1.5) for $n > 2$.** In this subsection we extend the results in §2.1 to high dimensions.

Let $u$ be a complete convex solution of (1.2). Let $\mathcal{M}_u$ denote the graph of $u$, and $D$ the projection of $\mathcal{M}_u$ on the plane $\{x_n = 0\}$. We divide $\mathcal{M}_u$ into two parts, $\mathcal{M}_u = \mathcal{M}^+ \cup \mathcal{M}^-$, where $\mathcal{M}^\pm = \{(x, u(x)) \in \mathbb{R}^{n+1} : \partial_n u(x) \gtrless 0\}$. Then $\mathcal{M}^+$ and $\mathcal{M}^-$ can be represented respectively as graphs of the form $x_n = g^+(x', x_{n+1})$ and $x_n = g^-(x', x_{n+1})$, where $x' = (x_1, \cdots, x_{n-1})$, $(x', x_{n+1}) \in D$. The functions $g^+$ and $g^-$ are respectively concave and convex, and satisfy the relation $x_{n+1} = u(x', g^\pm(x', x_{n+1}))$. As before we denote $g = g^+ - g^-$. Then $g$ is a positive, concave function in $D$, vanishing on $\partial D$.

For any $h > 0$ we also denote $g_h(x') = g(x', h)$, $g^\pm_h(x') = g^\pm(x', h)$, and $D_h = \{x' \in \mathbb{R}^{n-1} : (x', h) \in D\}$. Then $g_h$ is a positive, concave function in $D_h$, vanishing on $\partial D_h$, and $D_h$ is a convex domain in $\mathbb{R}^{n-1}$ containing the origin. Hence $\partial D_h$ can be represented as a radial graph of a positive function $a_h$ on $S^{n-2}$, $\partial D_h = \{p \cdot a_h(p) : p \in S^{n-2}\}$, where

$$a_h(p) = \sup\{t : t \cdot p \in D_h\}, \quad p \in S^{n-2}.$$  

Denote

$$\overline{\sigma}_h = \inf\{a_h(p) : p \in S^{n-2}\},$$

$$\underline{\sigma}_h = g_h(0).$$

We want to extend Lemma 2.3 to high dimensions, that is if $\underline{\sigma}_1(0)$ is small, then $u$ is defined in a strip region. First we prove a lemma which corresponds to Claim 1 in the proof of Lemmas 2.1 and 2.2.
Lemma 2.6. Let \( u \) be a complete convex solution of (1.2) satisfying \( u(0) = 0 \). Suppose \( \overline{a}_h \geq \overline{b}_h \). Then there is a positive constant \( C_n \), depending only on \( n \), such that

\[
(2.34) \quad \overline{a}_h \overline{b}_h \geq C_n h.
\]

Proof. When \( n = 2 \), (2.34) was proved in Claim 1 in Lemmas 2.1 and 2.2. When \( n \geq 3 \), we reduce (2.34) to the case \( n = 2 \).

Assume that \( \overline{a}_h = a_h(p) \) for \( p = (1, 0, \ldots, 0) \). Observing that \( \overline{a}_h \overline{b}_h \) is propositional to the area of the section \( \{ x \in \Omega_h : x_1 > 0, x_2 = \cdots = x_{n-1} = 0 \} \), we can prove (2.34) by making a rotation of coordinates. For a given \( h > 0 \), by a rotation of the coordinates we assume that \( \inf \{|x| : x \in \Gamma_{h,u}\} \) is attained at \( b^*e_n \), where \( b^* \in (0, \overline{b}_h] \) and \( e_k \) the unit vector in the \( x_k \)-axis, \( k = 1, \ldots, n \). Then it suffices to prove (2.34) for \( \overline{a}_h, \overline{b}_h \) defined in this new coordinate system. Since \( \overline{a}_h \geq \overline{b}_h \), by the convexity of \( \Gamma_{h,u} \) we have

\[
(2.35) \quad \Gamma_{h,u} \cap \{ |x| < \overline{a}_h \} \subset \{ |x_n| \leq 2\overline{b}_h \}.
\]

Let \( \hat{u} \) be the restriction of \( u \) on the 2-plane spanned by the \( x_1 \) and \( x_n \) axes. From the proof for the case \( n = 2 \) in Lemma 2.1, we see that (2.34) holds if one can verify that \( \mathcal{L}_0[\hat{u}] \leq C \) for some constant \( C \) depending only on \( n \), where \( \mathcal{L}_0 \) is the operator in (2.2).

For any given point \( y = (y_1, 0, \cdots, 0, y_n) \in \Gamma_{h,u} \), let \( \kappa \) be the mean curvature of \( \Gamma_{h,u} \), and \( \hat{k} \) be the curvature of \( \Gamma_{h,\hat{u}} \) at \( y \). Let \( \gamma = (\gamma_1, \gamma_2, \cdots, \gamma_n) \) be the unit normal of \( \Gamma_{h,u} \) at \( y \), and \( \hat{\gamma} = (\hat{\gamma}_1, 0, \cdots, 0, \hat{\gamma}_n) \) be the unit normal of \( \Gamma_{h,\hat{u}} \) at \( y \) in the 2-plane spanned by the \( x_1 \) and \( x_n \) axes. Suppose for a moment that

\[
(2.36) \quad \gamma \cdot \hat{\gamma} = \gamma_1 \hat{\gamma}_1 + \gamma_n \hat{\gamma}_n \geq C_1
\]

for some positive constant \( C_1 \). Then by the convexity of \( \Gamma_{h,u} \) we have \( \hat{k} \leq 2\kappa \) and \( \hat{k}_n \leq C_2u_n \). By (2.2), we have \( \kappa u_n \leq 1 \). Hence \( \mathcal{L}_0[\hat{u}] = \hat{k} \hat{u} \gamma \leq C \) and so (2.34) holds.

Let \( P = \{ x \in \mathbb{R}^n : \gamma \cdot (x - y) = 0 \} \) be the tangent plane of \( \Gamma_{h,u} \) at the point \( y \). Let \( p_k = z_k e_k \), \( k = 1, \cdots, n \), be the intersection of \( P \) with the \( x_k \)-axis. Then by \( \gamma \cdot (x - y) = 0 \) at \( x = p_k \), we have

\[
\gamma_k z_k = \gamma_1 y_1 + \gamma_n y_n \quad \forall \ k = 2, \cdots, n - 1
\]

Hence if for all \( k = 2, \cdots, n - 1 \), \( |z_k| \geq C \sqrt{y_1^2 + y_n^2} \), we have \( |\gamma_k| \leq \sqrt{\gamma_1^2 + \gamma_n^2} \), which implies \( \sqrt{\gamma_1^2 + \gamma_n^2} \geq C_1 > 0 \) as \( \gamma \) is a unit vector. Observe that the vector \( \langle \gamma_1, 0, \cdots, 0, \gamma_n \rangle \) is parallel to the unit vector \( \hat{\gamma} = (\hat{\gamma}_1, 0, \cdots, 0, \hat{\gamma}_n) \). Hence we obtain (2.36).

To prove \( |z_k| \geq C \sqrt{y_1^2 + y_n^2} \), notice that \( \gamma \) and \( \hat{\gamma} \) are invariant if we translate the level set \( \Gamma_{h,u} \). Without loss of generality let us assume that \( \gamma_n > 0 \). The case \( \gamma_n < 0 \) can be treated similarly. We translate \( \Gamma_{h,u} \) in the \( x_n \)-direction by a distance \( 2\overline{b}_h \), so that \( \Gamma_{h,u} \cap \{ |x| < \overline{a}_h \} \) is contained in \( \{ x_n > 0 \} \). Since \( P \) is a tangent plane of \( \Gamma_{h,u} \) lying above the set \( \Gamma_{h,u} \), we must have \( |z_k| \geq \overline{a}_h \). On the other hand, \( |y_1| \leq \overline{a}_h \) and \( |y_n| \leq 4\overline{b}_h \) (after the translation). Hence by the assumption \( \overline{b}_h \leq \overline{a}_h \), we have \( |z_k| \geq \frac{1}{2} \sqrt{y_1^2 + y_n^2} \). \( \square \)
Lemma 2.7. Let \( u \) be a complete convex solution of (1.2). Suppose \( u(0) = 0 \) and \( u(\beta e_n) \geq 1 \), \( u(-\beta e_n) \geq 1 \) for some sufficiently small \( \beta > 0 \), where \( e_n = (0, \cdots , 0, 1) \). Then \( u \) is defined in a strip region.

Note that the level set \( \Gamma_{h,u} = \{ u = h \} \) may not be compact. Note also that the strip region in Lemma 2.7 may not take the form \( \{ x \in \mathbb{R}^n : -C_1 \leq x_n \leq C_2 \} \), except in some special cases such as when \( u \) is symmetric in \( x_n \). But as in Lemmas 2.2 and 2.3, the axes of the minimum ellipsoid of \( \Omega_h \cap B_R(0) \) is a small perturbation of axes of the coordinates.

To prove Lemma 2.7 we will prove that the graph of \( g \), \( M_g = \{(x, x_{n+1}) : x_n = g(x', x_{n+1}), (x', x_{n+1}) \in D \} \), is contained in a strip \( \{(x, x_{n+1}) \in \mathbb{R}^{n+1} : 0 \leq x_n \leq C \} \). By convexity it suffices to prove \( \overline{b}_h = g_h(0) \) is uniformly bounded. The idea of our proof is very similar to the 2 dimensional case given in §2.1. In §2.1 we divided the proof into three lemmas. Here we present it in a single lemma.

Proof of Lemma 2.7. Let \( R = 10^3 \) and let \( E \) be the minimum ellipsoid of \( \Omega_1 \cap B_R(0) \). By a rotation of coordinates we assume the axial directions of \( E \) coincide with those of the coordinate system.

Denote \( h_k = 2^k, \overline{\alpha}_k = \overline{\alpha}_{h_k}, \overline{b}_k = \overline{b}_{h_k}, g_k = g_{h_k}, \) and \( D_k = D_{h_k} \). As in §2.1 we use induction argument to prove

\[
(2.37) \quad g_k(0) \leq g_{k-1}(0) + 2^{-k/4n} \quad \text{for all } k \geq 1.
\]

As shown in §2.1, (2.37) implies that \( u \) is defined in a strip region.

The proof of (2.37) is similar to (2.3), we point out the difference here. As in §2.1, when \( \beta \) is sufficiently small, by convexity we have \( \overline{b}_k \leq h_k \overline{b}_0 \leq 2^k \beta \leq 1 \) when \( k \leq k_0 \) and our induction argument starts at \( k = k_0 \).

Suppose by induction that (2.37) holds up to \( k \). By the induction assumption, \( g_k(0) \leq g_{k_0}(0) + \sum_{j=k}^{k_0} 2^{-j/4n} \leq 2 \). By the concavity, \( \overline{b}_{k+1} = g_{k+1}(0) \leq 2g_k(0) \leq 4 \). Hence by Lemma 2.6 we have

\[
(2.38) \quad \overline{\alpha}_{k+1} \geq C_0 h_{k+1}.
\]

Next we prove (2.37) at \( k + 1 \). Rotate the axes such that \( \partial_i g_k(0) \leq 0 \) for all \( i = 1, \cdots , n-1 \). By the concavity of \( g \) we have

\[
(2.39) \quad g_k(0) = \sup \{ g_k(x') : x_1 > 0, \cdots , x_{n-1} > 0 \}.
\]

Denote

\[
L_k = \{ x' \in \mathbb{R}^{n-1} : -\frac{C_0}{2n} h_k < x_i < \frac{C_0}{2n} h_k, i = 1, \cdots , n-1 \}.
\]

and \( Q_k = L_k \times [h_k, h_{k+1}] \subset D \), where \( C_0 \) is the constant in (2.38). Then similarly to (2.6),

\[
\sup \{ g(x', h) : (x', h) \in Q_k \} \leq 2 \sup \{ g(x', h_k) : x' \in L_k \} \leq 4g(0, h_k) \leq 8.
\]
Observing that \(2L_k \subset D_k\), by the convexity of \(u\) we have \(L_k \subset D_{k-1}\). Hence by the concavity of \(g\) and (2.39) we have, for any \((x', h) \in Q_k\),

\[
|\partial_h g(x', h)| \leq \frac{g(x', h) - g(x', h_{k-1})}{h - h_{k-1}} \leq \frac{g(x', h)}{h_k - h_{k-1}} \leq \frac{2g(x', h_k)}{h_k - h_{k-1}} \leq \frac{2g(0, h_k)}{h_k - h_{k-1}} \leq \frac{8}{h_k},
\]

By (2.38) and (2.39), the concavity of \(g\), and since \(g \geq 0\), we also have,

\[
|D_{x'} g(x', h)| \leq C/h_k \quad \forall (x', h) \in Q_k.
\]

From the above gradient estimates and the concavity of \(g\), the average in \(Q_k\) of the second order derivatives \(|\partial^2 g| \leq Ch_k^{-2}\). But we have not proved this estimate pointwise. We need to treat the set of points where \(|\partial^2 g|\) is relatively large. Denote

\[
\chi = \{(x', h) \in Q_k : |\Sigma_{i=1}^{n-1} \partial_i^2 g_h(x')| \geq h_k^{-5/4}\},
\]

\[
\chi^+ = \{(x', h) \in Q_k : |\Sigma_{i=1}^{n-1} \partial_i^2 g_h^+(x')| \geq h_k^{-5/4}\}.
\]

Obviously \(\chi^+ \subset \chi\). By the gradient estimates, we have

\[
|\chi|_{\mathcal{H}^n h_k^{-5/4}} \leq \int_{Q_k} |\Delta_{x'} g| \leq \int_{\partial L_k \times [h_k, h_{k+1}]} |D_{x'} g| \leq Ch_k^{n-2}.
\]

In the above formula \(g\) is a function of \((x', h)\). Hence we obtain

\[
|\chi^+|_{\mathcal{H}^n} \leq |\chi|_{\mathcal{H}^n} \leq Ch_k^{n-3/4}.
\]

From (2.43) and by the Fubini Theorem, there is a set \(\tilde{L} \subset L_k\) with measure \(|\tilde{L}|_{\mathcal{H}^{n-1}} < h_k^{n-3/2}\) such that for any \(y' \in L_k - \tilde{L}\),

\[
|\chi^+_{y'}|_{\mathcal{H}^1} \leq Ch_k^{3/4},
\]

where \(\chi^+_{y'} = \chi^+ \cap \{x' = y'\}\).

For any given \(y' \in L_k - \tilde{L}\), we want to prove

\[
g_{k+1}^+(y') - g_k^+(y') \leq Ch_k^{-1/4}.
\]

Similarly we can estimate \(|g_{k+1}^-(y') - g_k^-(y')|\). Hence if (2.45) is proved, we have

\[
g_{k+1}(y') - g_k(y') \leq Ch_k^{-1/4},
\]
which corresponds to (2.15). As the argument after (2.15), we can choose a point \(y_1 \in L_k - \tilde{L}\) with \(|y_1| \leq C h_k^{1/2} \) such that \(g_{k+1}(y_1) \leq g_k(0) + C h_k^{-1/4}\). But now
\[
\frac{g_{k+1}(0)}{g_{k+1}(y_1)} \leq \frac{\bar{a}_{k+1}}{\bar{a}_{k+1} - |y_1|} \leq 1 + C h_k^{-1/2}.
\]
Therefore we obtain (2.37).

To prove (2.45), we have
\[
g_{k+1}^+(y') - g_k^+(y') = \int_I \partial_h g^+(y', h) dh
\]
where as in (2.24), \(I = (h_k, h_{k+1}), I_1 = \chi^+ \cap \{x' = y'\}, I_2 = \{h \in I - I_1 : \frac{\sigma u_{y_1}^+(q)}{\sigma + u_{y_1}^+(q)} \leq \frac{1}{2}\}, \) and \(I_3 = I - (I_1 \cup I_2)\), where \(q = T(p)\) with \(p = (y', h)\), and \(T : p \rightarrow q\) is the mapping introduced before (2.21).

For the first integral in (2.46), by (2.40) and (2.44) we have
\[
\int_{I_1} \partial_h g^+(y', h) dh \leq C h_k^{-1/4}
\]
Note that in \(I_2\), similarly to (2.23) we have
\[
|\partial_h g^+(y_1, h)| \leq C |\partial x_1 x_1, g^+| \leq C h_k^{-5/4} \forall (y_1, h) \notin \chi^+.
\]
Hence we have the estimate for the second integral in (2.46),
\[
\int_{I_2} \partial_h g^+(y', h) dh \leq C h_k^{-1/4}.
\]
For the third one, the argument between (2.25) and (2.29) applies and we also have the estimate \(\text{osc}_{I_3} g^+ \leq C/h_k\). Hence (2.45) holds.

The next lemma corresponds to Lemma 2.4 in §2.1.

**Lemma 2.8.** Let \(u\) be a complete convex solution of (1.2). Suppose \(u(0) = 0\) and the infimum \(\inf\{|x| : x \in \Gamma_1\}\) is attained at \(x_0 = (0, \cdots, 0, -\delta) \in \Gamma_1\) for some \(\delta > 0\) sufficiently small. As above let \(D_1\) be the projection of \(\Gamma_1\) on the plane \(\mathbb{R}^n \cap \{x_n = 0\}\). Then \(D_1 \supset \{x' \in \mathbb{R}^{n-1} : |x'| < R\}\) with
\[
R \geq \frac{1}{C_n} (-\log \delta - C)^{1/2},
\]
where \(C_n\) is a constant depending only on \(n\), and \(C > 0\) is a constant independent of \(\delta\).

*Proof.* Estimate (2.47) is equivalent to \(a_1(p) \geq \frac{1}{C_n} (-\log \delta - C)^{1/2}\) for any \(p \in S^{n-2}\). Suppose \(\inf a_1(p)\) is attained at \(p = (1, 0, \cdots, 0)\). By restricting \(u\) to the 2-plane \(\{x_2 = \cdots = x_{n-1} = 0\}\), we reduce the proof to the 2 dimensional case in Lemma 2.4, as we have shown, in the proof of Lemma 2.6, that \(L_0[u] \leq C_n\).

With Lemmas 2.7 and 2.8, we extend Theorem 2.1 to high dimensions.
Theorem 2.2. Let $u$ be an entire convex solution of (1.2) in $\mathbb{R}^n$. Then there exists a positive constant $C$ such that for any $x \in \mathbb{R}^n$,

\begin{equation}
(2.48) \quad u(x) \leq C(1 + |x|^2),
\end{equation}

where $C$ depends on $n$ and the upper bound of $u(0)$ and $|Du(0)|$.

Proof. The proof is very similar to that of Theorem 2.1. Let $\delta, \delta^*$ and $u_h$ be as in the proof of Theorem 2.1. Instead of an ellipse, here we use the ellipsoid

$$E = \{ x \in \mathbb{R}^2 : \sum_{i=1}^{n-1} \frac{x_i^2}{(R/2n)^2} + \frac{|x_2 - (\delta^* - \delta)/2|^2}{[(\delta^* + \delta)/8]^2} < 1 \}.$$ 

When $\sigma = 0$, the level set $\Gamma_{-t,u_h}$ is a solution to the mean curvature flow. Let $E_{-t}$ be the solution to the mean curvature flow with initial condition $E_{-1} = E$, so that $E_{-t} \subset \Omega_{-t,u_h}$ for all $t > -1$. Suppose it takes time $T$ for $E_{-t}$ to shrink to a point. Then we have $\inf_{B_t(0)} u_h \leq 1 - T$. Observe that for any fixed $\delta^*$, $E_{-t}$ converges to a pair of parallel planes, and so $T \to \infty$ as $R \to \infty$ (or $\delta \to 0$). Hence when $\delta$ is small, we reach a contradiction with the assertion that $\inf_{B_t(0)} u_h$ is uniformly bounded from below. The case $\sigma > 0$ can be proved in the same way as in Theorem 2.1. \qed

From Theorem 2.2, we have accordingly

Corollary 2.2. Let $u$ be a complete convex solution of (1.2). Then $u$ is either an entire solution, or is defined in a strip region. There is no complete convex solution of (1.2) defined in a half space.

Note that estimate (2.48) also implies the follows compactness result. This compactness result is not just for the set of blow-up solutions to mean convex flow but for all entire convex solutions of (1.2). We don’t know whether an entire convex solution to (1.2) must be a blow-up solution to mean convex flow.

Corollary 2.3. For any constant $C > 0$, the set of all entire convex solutions $u$ to (1.2) satisfying $u(0) = 0$ and $|Du(0)| \leq C$ is compact.

2.3. Proof of Theorem 1.3. First we prove a lemma.

Lemma 2.9. Let $u$ be an entire convex solution of (1.2). Suppose $u \geq 0$ and $u(0) = 0$. Then the convex set $\{ u = 0 \}$ is either a single point or it is a linear subspace of $\mathbb{R}^n$.

Proof. If $\sigma > 0$, $u$ is analytic. As the set $\{ u = 0 \}$ is convex, it must be a single point or a linear subspace of $\mathbb{R}^n$. In the following we consider the case $\sigma = 0$.

If the set $\{ u = 0 \}$ is bounded, then $\Gamma_{h,u}$ is a closed, bounded convex hypersurface. As $\Gamma_{h,u}$ evolves by mean curvature (with time $t = -h$). From [8, 12] it follows that $\{ u = 0 \}$ is a single point.
If the set \( \{ u = 0 \} \) contains a straight line, say the line \( \ell = (t, 0, \cdots, 0) \ (t \in \mathbb{R}) \), then by convexity \( u \) is independent of \( x_1 \). Hence to prove Lemma 2.9, we need only to rule out the possibility that \( \{ u = 0 \} \) contains a ray but no straight line lies in it.

Suppose the ray \( r = (t, 0, \cdots, 0) \ (t > 0) \) is contained in \( \{ u = 0 \} \). We may also suppose that \( \{ u = 0 \} \) contains no straight lines and the asymptotical cone of \( \{ u = 0 \} \) is contained in \( \{ x_1 > 0 \} \). Then \( u \) is decreasing in \( x_1 \). Denote \( u_m(x_1, x_2, \cdots, x_n) = u(x_1 + m, x_2, \cdots, x_n), \) where \( m > 0 \) is a constant. Then \( u_m \) is nonnegative and decreasing in \( m \). By choosing a subsequence we suppose \( u_m \to \hat{u} \) as \( m \to \infty \). Then the straight line \( \ell = (t, 0, \cdots, 0) \ (t \in \mathbb{R}) \) is contained in the graph of \( \hat{u} \). By convexity, \( \hat{u} \) is independent of \( x_1 \). Since \( \mathcal{L}_0[\hat{u}] = 1, \hat{u} \) does not vanish completely, and so we must have \( n \geq 3 \). Moreover, we have \( \hat{u} < u \) except on the set \( \{ u = \hat{u} = 0 \} \).

Since \( u \) and \( \hat{u} \) are both solutions to \( \mathcal{L}_0[u] = 1 \), the level sets \( \{ u = -t \} \) and \( \{ \hat{u} = -t \} \) evolve by mean curvature (with time \( t \)). Denote \( \mathcal{M}_t = \{ u = -t \} \cap \{ x_1 = 0 \} \) and \( \hat{\mathcal{M}}_t = \{ \hat{u} = -t \} \cap \{ x_1 = 0 \} \). Then \( \hat{\mathcal{M}}_t \) evolves by mean curvature as \( \hat{u} \) is independent of \( x_1 \). We assert that \( \mathcal{M}_t \) evolves at a velocity greater than its mean curvature. Indeed, for any given point \( p \in \mathcal{M}_t \), we assume the hypersurface \( \{ u = -t \} \) is locally given by \( x_n = \psi(x_1, \cdots, x_{n-1}) \), and locally \( \mathcal{M}_t \) is given by \( x_n = \psi(0, x_2, \cdots, x_{n-1}) \). By choosing the coordinate system properly we also assume that \( \partial_{x_i} \psi = 0 \) for \( i = 2, \cdots, n - 1 \) at \( p \). Then \( \mathcal{M}_t \) evolves at the velocity \( \sqrt{1 + |D\psi|^2} \) by convexity which is greater than \( \sum_{i=2}^{n-1} \partial_{x_i}^2 \psi \), the mean curvature of \( \mathcal{M}_t \) at \( p \).

On the other hand, since \( \hat{u} < u \), \( \mathcal{M}_t \) is strictly contained in the interior of \( \hat{\mathcal{M}}_t \) for any \( t < 0 \). Moreover \( \mathcal{M}_t \) is a bounded, closed convex hypersurface, as the asymptotical cone of \( \{ u = 0 \} \) is contained in \( \{ x_1 > 0 \} \). By the comparison principle, \( \mathcal{M}_t \) is strictly contained in the interior of \( \hat{\mathcal{M}}_t \) for all \( t \leq 0 \). We reach a contradiction as \( \hat{u} = u = 0 \) at the origin. \( \square \)

Therefore by [12], Lemma 2.9 implies that the singularity set of a mean curvature flow of convex, noncompact hypersurfaces in \( \mathbb{R}^{n+1} \) must be a subspace \( \mathbb{R}^{n-k} \) for some \( 1 \leq k \leq n \). But then by convexity, \( u \) is a function of \( k \) variables.

**Proof of Theorem 1.3.**

**Step 1.** First we prove that there is a subsequence of \( u_h \), where \( u_h(x) = h^{-1}u(h^{1/2}x) \), which converges to \( \eta_k \) for some \( 2 \leq k \leq n \), where \( \eta_k \) is the function given in (1.4).

By adding a constant we may suppose \( u(0) = 0 \). Let \( T = \{ x_{n+1} = a(x) \} \) be the tangent plane of \( u \) at the origin. By Theorems 2.1 and 2.2 and the convexity of \( u \) we have

\[
a(x) \leq u(x) \leq C(1 + |x|^2).
\]

Hence

\[
\frac{1}{\sqrt{h}} a(x) \leq u_h(x) \leq C\left(\frac{1}{\sqrt{h}} + |x|^2\right).
\]

By convexity it follows that \( Du_h \) is locally uniformly bounded. Hence \( u_h \) sub-converges to
a convex function \( u_0 \) which satisfies \( u_0(0) = 0 \),

\[
0 \leq u_0(x) \leq C|x|^2.
\]

By Lemma 2.5, \( u_0 \) is an entire convex solution of \( L_0[u] = 1 \).

Case 1: the set \( \{ x \in \mathbb{R}^n : u_0(x) = 0 \} \) is bounded. Then by convexity the level set \( \Gamma_{1,u_0} = \{ x \in \mathbb{R}^n : u_0(x) = 1 \} \) is a bounded convex hypersurface. Since the level set \( \{ u_0 = -t \} \), with time \( t \in (-\infty, 0) \), evolves by mean curvature, by the asymptotic estimates in [8, 12],

\[
u_0(x) = \frac{1}{2(n-1)}|x|^2 + \varphi(x)
\]

where \( \varphi(x) = o(|x|^2) \) for \( x \neq 0 \) near the origin. Hence for any \( \varepsilon > 0 \), there is a sufficiently small \( h' > 0 \), such that

\[
B_{(1-\varepsilon)r}(0) \subset \Omega_{h',u_0} \subset B_{(1+\varepsilon)r}(0),
\]

where \( r = \sqrt{2(n-1)h'} \). Hence there is a sequence \( h_m \to \infty \) such that

\[
B_{(1-\frac{1}{m})r_m}(0) \subset \Omega_{h_m,u} \subset B_{(1+\frac{1}{m})r_m}(0),
\]

where \( r_m = \sqrt{2(n-1)h_m} \). Let \( u_{h_m}(x) = \frac{1}{h_m}u(\sqrt{h_m}x) \). Then \( u_{h_m} \) sub-converges to \( \hat{u}_0 \) which satisfies \( L_0[\hat{u}_0] = 1 \). From (2.51), the level set \( \Gamma_{1,\hat{u}_0} \) is a sphere. Hence \( \hat{u}_0(x) = \frac{1}{2(n-1)}|x|^2 \).

Case 2: the set \( \{ u_0 = 0 \} \) is unbounded. Then by Lemma 2.9, the set \( \{ u_0 = 0 \} \) is a linear sub-space of \( \mathbb{R}^n \). Suppose \( \{ u_0 = 0 \} = \{ x \in \mathbb{R}^n : x_{k+1} = \cdots = x_n = 0 \} \). We must have \( k \geq 2 \), as the level set \( \{ u_0 = -t \} \) evolves by its mean curvature. It follows that \( u_0 \) is a convex function depending only on \( \hat{x} = (x_1, \cdots, x_k) \). Similarly as above we have

\[
u_0(x) = \frac{1}{2(k-1)}|\hat{x}|^2 + o(|\hat{x}|^2)
\]

near the origin. Hence for any \( \varepsilon > 0 \),

\[
\hat{B}_{(1-\varepsilon)r}(0) \subset \hat{\Omega}_{h',u_0} \subset \hat{B}_{(1+\varepsilon)r}(0)
\]

provided \( h' \) is sufficiently small, where \( r = \sqrt{2(k-1)h'} \), \( \hat{B}_r(0) = B_r(0) \cap \{ \tilde{x} = 0 \} \) and \( \hat{\Omega}_{h',u} = \Omega_{h',u} \cap \{ \tilde{x} = 0 \} \), \( \tilde{x} = (x_{k+1}, \cdots, x_n) \). It follows that for any \( R > 0 \),

\[
\{ x \in \mathbb{R}^n : |\hat{x}| < (1-\varepsilon)r \} \cap \{ |\tilde{x}| < R \} \subset \Omega_{h',u_{h_m}} \cap \{ |\tilde{x}| < R \}
\]

\[
\subset \{ x \in \mathbb{R}^n : |\hat{x}| < (1+\varepsilon)r \} \cap \{ |\tilde{x}| < R \}
\]
if $h_m$ is sufficiently large. Hence there exist $\tau_m \to \infty$ and (a different sequence) $h_m \to \infty$ such that

\begin{equation}
\{ x \in \mathbb{R}^n : |\hat{x}| < (1 - \frac{1}{m})r_m \} \cap \{ |\tilde{x}| < \tau_m r_m \}
\subset \Omega_{h_m,u} \cap \{ |\tilde{x}| < \tau_m r_m \}
\subset \{ x \in \mathbb{R}^n : |\hat{x}| < (1 + \frac{1}{m})r_m \} \cap \{ |\tilde{x}| < \tau_m r_m \},
\end{equation}

where $r_m = \sqrt{2(k-1)h_m}$. Hence $u_{h_m} \to \frac{1}{2(k-1)}|\hat{x}|^2$.

**Step 2.** Now we prove that $u_h$ itself, after a rotation of axes, converges to the function $\eta_k$.

In Step 1 we proved that $u_{h_m}$ converges to $\eta_k$ for some $2 \leq k \leq n$. Let us choose the sequence $\{h_m\}$ properly such that $k$ is the largest such integer, namely if $u_{h_m'}$ converges to $\eta_{k'}$, then $k' \leq k$. From the above proof we can also choose $h_m$ such that (2.51) or (2.53) holds.

**Case 1:** $k = n$. We prove that for any constant $\varepsilon > 0$,

\begin{equation}
B_{(1-\varepsilon)r}(0) \subset \Omega_{h,u} \subset B_{(1+\varepsilon)r}(0)
\end{equation}

if $h > 0$ is sufficiently large, where $r = \sqrt{2(n-1)h}$. Suppose (2.54) is not true. Let $h_m \to \infty$ be a sequence such that (2.51) holds. Let

\begin{equation}
\hat{h}_m = \inf\{ h' \leq h_m : (2.54) \text{ holds for any } h \in (h', h_m) \}.
\end{equation}

Since $u_{h_m} \to \frac{1}{2(n-1)}|x|^2$, we have $h_m/\hat{h}_m \to \infty$ as $m \to \infty$. Let $\alpha > 1$ be a fixed constant which will be determined below. Then the sequence $u_{\alpha\hat{h}_m}$ sub-converges to a convex function $u_0$ satisfying $u_0(0) = 0$, $u_0 \geq 0$ and $\mathcal{L}_0[u] = 1$. By our choice of $\hat{h}_m$, the level set $\Omega_{1,u_0}$ satisfies

\begin{equation}
B_{(1-\varepsilon)r}(0) \subset \Omega_{1,u_0} \subset B_{(1+\varepsilon)r}(0)
\end{equation}

with $r = \sqrt{2(n-1)}$. Hence from [8, 12], the level set $\Omega_{h,u_0}$ satisfies

\begin{equation}
B_{(1-\delta)r}(0) \subset \Omega_{h,u_0} \subset B_{(1+\delta)r}(0)
\end{equation}

with $\delta \to 0$ as $h \to 0$, where $r = \sqrt{2(n-1)h}$. Hence we have

\begin{equation}
B_{(1-2\delta)r}(0) \subset \Omega_{h,u_{\alpha\hat{h}_m}} \subset B_{(1+2\delta)r}(0)
\end{equation}

if $m$ is sufficiently large. Choose $h$ sufficiently small such that $\delta \leq \frac{1}{3}\varepsilon$ and let $\alpha = h^{-1}$. Then scaling back we find that $\Omega_{h_m,u}$ satisfies

\begin{equation}
B_{(1-2\delta)r_m}(0) \subset \Omega_{h_m,u} \subset B_{(1+2\delta)r_m}(0)
\end{equation}

for sufficiently large $m$.
with \( r = \sqrt{2(n-1)\hat{h}_m} \). When \( \delta < \frac{1}{2}\varepsilon \), this is in contradiction with our choice of \( \hat{h}_m \).

Case 2: \( k < n \). For any given small \( \varepsilon > 0 \), by (2.53), \( \Gamma_{h_m,u} \) is \( \varepsilon \)-close to the cylinder \( S^{k-1} \times \mathbb{R}^{n-k} \) if \( m \) is sufficiently large, namely

\[
\{ x \in \mathbb{R}^n : |\hat{x}| < (1-\varepsilon)r \} \cap \{|\tilde{x}| < \varepsilon^{-1}r \}
\subset \Omega_{h_m,u} \cap \{|\tilde{x}| < \varepsilon^{-1}r \}
\subset \{ x \in \mathbb{R}^n : |\hat{x}| < (1+\varepsilon)r \} \cap \{|\tilde{x}| < \varepsilon^{-1}r \},
\]

where \( r = \sqrt{2(k-1)\hat{h}_m} \). Let \( \hat{h}_m < h_m \) be the least number such that \( \Gamma_{h,u} \) is \( \varepsilon \)-close to the cylinder \( S^{k-1} \times \mathbb{R}^{n-k} \) (the axes of the cylinder may vary as \( h \) varies) for any \( h \in [\hat{h}_m, h_m] \). Then by our assumption that \( k \) is the largest possible integer, we have, due to (2.52), that \( u_{\alpha \hat{h}_m} = \frac{1}{2(k-1)}|\hat{x}|^2 + o(|\hat{x}|^2) \) for any given \( \alpha > 1 \). Here we regard \( u_{\alpha \hat{h}_m} \) as a function of \( \hat{x} = (x_1, \cdots, x_k) \) by letting \( x_{k+1} = \cdots = x_n = 0 \). Similar to Case 1, we can choose \( \alpha > 1 \) such that \( \Gamma_{\hat{h}_m,u} \) is \( \frac{1}{2}\varepsilon \)-close to the cylinder \( S^{k-1} \times \mathbb{R}^{n-k} \), which is in contradiction with our choice of \( \hat{h}_m \). Hence Theorem 1.3 is proved. □

Note that Case 2 in Step 2 follows readily from Step 1 and the fact that \( k \) is an integer. In Step 1 it is shown that \( u_h \) converges along a subsequence to the function \( \eta_k \) but \( k \) is an integer so it must be the same integer for all subsequences.

**Remark 2.2.** Theorem 1.3 asserts that \( u_h \), which is the blow-down of \( u \) with respect to the origin in space-time, sub-converges to a self-similar solution. We point out that for ancient convex solutions \( w \) to the level set flow (1.2) (with \( \sigma = 0 \)), under some very mild conditions the corresponding level set \( \{ w = h \} \), after proper translation, sub-converges as \( h \to \infty \) to a translating solution. In particular, if \( w \) is a complete convex solution of (1.2) defined in a strip region in \( \mathbb{R}^2 \), then after proper translation, the level set must converge along a subsequence to the grim reaper.

### 3. Proof of Theorem 1.1

In this section we prove Theorem 1.1. Throughout this section we suppose the dimension \( n = 2 \).

Let \( u \) be an entire convex solution of (1.2). By Theorem 1.3 we have

\[
(3.1) \quad u(x) = \frac{1}{2}|x|^2 + \varphi(x)
\]

with \( |\varphi(x)| = o(|x|^2) \) as \( |x| \to \infty \). To prove Theorem 1.1, we first consider the case \( \sigma = 0 \).

**Theorem 3.1.** Let \( u \) be an entire convex solution of (1.2) with \( \sigma = 0 \). Then \( u(x) = \frac{1}{2}|x|^2 \) in a proper coordinate system.
Proof. By a translation of the graph of $u$, we may suppose $u \geq 0$, $u(0) = 0$, and (3.1) holds. For any constant $h > 1$, denote $u_h(y) = u(h^{1/2}y)/h$. Then $u_h$ is also an entire convex solution of (1.2) and by (3.1), the sub-level set $\Omega_{1/2,u_h}$ satisfies

\[
B_{1-\varepsilon}(0) \subset \Omega_{1/2,u_h} \subset B_{1+\varepsilon}(0)
\]

with $\varepsilon \to 0$ as $h \to \infty$. By Gage-Hamilton [8], we have

\[
u_h(y) = \frac{1}{2}|y|^2 + \varphi(y)
\]

with

\[|\varphi(y)| \leq C|y|^{2+\alpha}\]

for some $\alpha \in (0,1)$, and $C$ is a constant independent of $h$. Rescaling back to the $x$-coordinate we obtain

\[u(x) = \frac{1}{2}|x|^2 + h^2\varphi(x/h),\]

where for any fixed $x$, $h^2\varphi(x/h) \to 0$ as $h \to \infty$. Hence $u(x) \equiv \frac{1}{2}|x|^2$. \qed

Remark 3.1. By the asymptotic estimates in [12], Theorem 3.1 also holds in high dimensions if the solution $u$ satisfies

\[
C_1|x|^2 \leq u(x) \leq C_2|x|^2.
\]

Indeed, if $u$ satisfies (3.4), we have $u(x) = \frac{1}{2(n-1)}|x|^2 + o(|x|^2)$ by Theorem 1.3. Next we consider the case $\sigma = 1$ of Theorem 1.1.

Theorem 3.2. Let $u$ be an entire convex solution of the mean curvature equation (1.1). Then $u$ is rotationally symmetric in an appropriate coordinate system.

To prove Theorem 3.2 we need a few lemmas.

Lemma 3.1. Let $\Omega$ be a bounded convex domain in $\mathbb{R}^2$. Let $u_0$ and $u_\sigma$ be respectively solutions of $L_0[u] = 1$ and $L_\sigma[u] = 1$ in $\Omega$, vanishing on $\partial \Omega$, where $\sigma \in (0,1]$. Suppose $u_\sigma$ is convex. Then for any constant $a > 0$, there exists a constant $C > 0$, depending on $a$ and the upper and lower bounds of $|Du_\sigma|$ on the set $\{x \in \Omega : \inf u_\sigma + a \leq u_\sigma(x) < 0\}$, such that for any $0 > h > a + \inf_{\Omega} u_\sigma$,

\[
0 \leq |\Omega_{h,u_0}| - |\Omega_{h,u_\sigma}| \leq C\sigma.
\]

Note that the constant $C$ in (3.5) is large when the lower bound of $|Du_\sigma|$ is small. We don’t impose condition on $\Omega$ but it is convex and its shape is controlled by the lower bound of $|Du_\sigma|$.
For the proof of Theorem 1.1, the solution $u$ satisfies (3.1) and $\Omega$ is a small perturbation of the unit disc. In this case (3.5) can be proved easily. In fact, the difference $|\Omega_{h,u_0}| - |\Omega_{h,u_0}| = O(\sigma)$, see (3.6) below.

**Proof.** Denote $u = u_\sigma$ and suppose without loss of generality that $u(0) = \inf_{\Omega} u = -1$. By convexity we have $L_0[u] \leq 1$. By the comparison principle we have $u \geq u_0$. Hence $\Omega_{h,u} \subset \Omega_{h,u_0}$ and $|\Omega_{h,u_0}| \geq |\Omega_{h,u}|$.

Write the equation $L_\sigma[u] = 1$ in the form

\[(3.6) \quad \kappa u_\gamma = 1 - \frac{\sigma u_{\gamma\gamma}}{\sigma + u_\gamma^2},\]

where $\kappa$ is the curvature of the level set $\Gamma_{h,u}$, and $\gamma$ is the unit outward normal to $\Omega_{h,u}$. (3.6) implies that the level set $\Gamma_{h,u}$ is moving with the velocity (regard $t = -h$ as the time)

\[v = u_\gamma^{-1} = \frac{\kappa}{1 - \frac{\sigma u_{\gamma\gamma}}{\sigma + u_\gamma^2}}.\]

Let $w = w(\cdot, h) \in C(S^1)$ denote the supporting function of $\Gamma_{h,u}$. That is,

\[w(p) = w(p, h) = \sup \{ \langle p, x \rangle : x \in \Gamma_{h,u} \} \quad p \in S^1.\]

The supremum is attained at the point $x$ at which the unit outer normal $\gamma(x) = p$, and the curvature $\kappa$ at $x$ is given by

\[\kappa(x) = \frac{1}{(w'' + w)(p)} ;\]

where $S^1$ is parametrized by $p = (\cos \theta, \sin \theta)$ and $w' = \frac{d}{d\theta} w$. The area of the domain $\Omega_{h,u}$ is given by

\[|\Omega_{h,u}| = \frac{1}{2} \int_{S^1} w(w'' + w).\]

Observing that $\partial_h w = v = u_\gamma^{-1}$, we have

\[(3.7) \quad \frac{d}{dh} |\Omega_{h,u}| = \frac{d}{dh} \int_{S^1} \frac{1}{2} w(w'' + w) = \int_{S^1} \partial_h w(w'' + w) = \int_{S^1} \frac{\kappa}{1 - \frac{\sigma u_{\gamma\gamma}}{\sigma + u_\gamma^2}} (w'' + w).\]

For any $h \in (a + \inf_{\Omega} u, 0)$, denote $D = S^1 \times (h, 0)$. Let $G$ denote the diffeomorphism from $\mathcal{M}_{u,h} =: M_u \cap \{h < u < 0\}$ to $D$, where $M_u$ is the graph of $u$, such that for any
point \((x, t) \in \mathcal{M}_{u, h}\), \(G(x, t) = (G_t(x), t) \in D\), where \(G_t\) is the Gauss mapping from the level set \(\Gamma_{t, u}\) to \(S^1\).

We divide \(D\) into two parts, \(D = D_1 \cup D_2\), such that

\[
D_1 = \left\{1 - \frac{\sigma u_{\gamma \gamma}}{\sigma + u_\gamma^2} \geq \frac{1}{2}\right\}
\]

and \(D_2 = D - D_1\). Observing that \(\kappa(w'' + w) = 1\), from (3.7) we have

\[
|\Omega_{0,u}\| - |\Omega_{h,u}| = \int_{D_1} \frac{1}{1 - \frac{\sigma u_{\gamma \gamma}}{\sigma + u_\gamma^2}} + \int_{D_2} \frac{\kappa}{1 - \frac{\sigma u_{\gamma \gamma}}{\sigma + u_\gamma^2}} (w'' + w).
\]

On \(D_1\) we have

\[
(1 - \frac{\sigma u_{\gamma \gamma}}{\sigma + u_\gamma^2})^{-1} \leq 1 + \frac{2\sigma u_{\gamma \gamma}}{\sigma + u_\gamma^2} \leq 1 + C_1 \sigma u_{\gamma \gamma},
\]

on \(D_2\) we have

\[
(3.8) \quad \frac{\kappa}{1 - \frac{\sigma u_{\gamma \gamma}}{\sigma + u_\gamma^2}} = u_\gamma^{-1} \leq C^{-1}_2,
\]

where both constants \(C_1\) and \(C_2\) depend on the lower bound of \(|Du|\) on the set \(\{u > a + \inf u\}\). Hence

\[
(3.9) \quad |\Omega_{0,u}| - |\Omega_{h,u}| \leq \int_{h} \int_{S^1} (1 + C \sigma u_{\gamma \gamma}) + C \int_{D_2} (w'' + w)
\]

\[
= 2\pi |h| + C \sigma \int_{h} \int_{S^1} u_{\gamma \gamma} + C |G^{-1}(D_2)|
\]

\[
\leq 2\pi |h| + C \sigma + C |G^{-1}(D_2)|
\]

To estimate \(|G^{-1}(D_2)|\) we suppose \(\inf u\) is attained at the origin. For any unit vector \(\tau\) in the plane \(\{x_3 = 0\}\) starting at the origin, let \(P_\tau\) be the plane in \(\mathbb{R}^3\) containing \(\tau\) and the \(x_3\)-axis, and let \(E_\tau\) denote the intersection of \(P_\tau\) with \(G^{-1}(D_2)\). On \(E_\tau\) we have, by our definition of \(D_2\), \(u_{\gamma \gamma} \geq \frac{C}{\sigma}\). Noting that by equation, \(u_{\xi \xi} \leq C\) in \(G^{-1}(D_2)\) for any unit vector tangential to \(\Gamma_{h,u}\) and that the inner product \(\langle \gamma, \tau \rangle \geq C\) for some constants \(C, C' > 0\) depending on the upper and lower bounds of \(|Du|\) on the set \(\{x \in \Omega : \inf u + a \leq u(x) < 0\}\) (which also determine the geometric shape of \(\Omega\), we have \(u_{\tau \tau} \geq \frac{C}{\sigma}\) for a different \(C\) (for small \(\sigma > 0\)). It follows that the one dimensional Lebesgue measure \(|E_\tau|_{H^1} \leq C\sigma\) for some \(C\) depending on the upper bound of \(|Du|\). Hence the two dimensional Lebesgue measure

\[
|G^{-1}(D_2)|_{H^2} \leq C\sigma.
\]

Observing that the level set \(\Gamma_{h,u_0}\) is moving by its curvature (with time \(t = -h\)), we have

\[
|\Omega_{0,u_0}| - |\Omega_{h,u_0}| = 2\pi |h|.
\]

Hence by (3.9),

\[
|\Omega_{h,u_0}| - |\Omega_{h,u}| \leq C\sigma + C |G^{-1}(D_2)| \leq C\sigma.
\]

We obtain (3.5). \(\Box\)
Lemma 3.2. Let \( \{\ell_t\} \) be a convex solution to the curve shortening flow. Suppose \( \ell_0 \) is in the \( \delta_0 \)-neighborhood of a unit circle \( S^1 \) and \( \{\ell_t\} \) shrinks to a point (the origin) at \( t = \frac{1}{2} \). Let \( \hat{\ell}_t = \frac{1}{\sqrt{1-2t}} \ell_t \) be the normalization of \( \ell_t \). Then \( \hat{\ell}_t \) is in the \( \delta_t \)-neighborhood of the unit circle centered at the origin,

\[
\hat{\ell}_t \subset N_{\delta_t}(S^1),
\]

with

\[
\delta_t \leq C\delta_0 \left( \frac{1}{2} - t \right)^\alpha,
\]

where \( \alpha \in (0, 1) \) is a positive constant.

Proof. First observe, by the comparison principle, that when \( t \leq \frac{1}{4} \), \( \ell_t \) is pinched between two concentrated circles with Hausdorff distance \( C\delta_0 \). By the Schauder estimate, for \( t \in \left( \frac{1}{8}, \frac{1}{4} \right) \) the \( C^k \) norm of \( \hat{\ell}_t \) is in the \( C\delta_0 \)-neighborhood of the unit circle, that is

\[
\| \hat{\ell}_t - S^1 \|_{C^k} \leq C\delta_0.
\]

With estimate (3.11) we obtain (3.10) from [8], §5.7.10–§5.7.15. □

Remark 3.2 (i). By the Schauder estimate one can simplify some estimates in [8], §5.1–5.6. In [8], §5.7.10–§5.7.15, it was proved that for any \( \alpha > 0 \) small, there exists \( \delta_0 > 0 \) such that if (3.11) holds at \( t = 0 \), then

\[
\int_{S^1} [\kappa'(\tau)]^2 \leq e^{-\alpha \tau} \int_{S^1} [\kappa'(0)]^2,
\]

where \( \tau = \frac{1}{2} \log(\frac{1}{2} - t) \), and \( \kappa' \) denotes the derivative of the curvature \( \kappa \) with respect to the arc-length parameter. Similar inequalities for high order derivatives of \( \kappa \) were also proved there.

(ii) Let \( u \) be a convex solution of \( L_0[u] = 0 \) which attains its minimum 0 at \( y_1 \) (namely \( u(y_1) = \inf u = 0 \)). Suppose the level set \( \Gamma_{1/2} \subset N_{\delta_0}(S^1) \) for some small \( \delta_0 > 0 \). Then \( |y_1| < C\delta_0 \) for some \( C > 0 \) independent of \( \delta_0 \). Therefore by a translation we may assume that \( u \) attains its minimum at 0 and \( \Gamma_{1/2,u} \subset N_{C^\ast \delta_0}(S^1) \) for a different constant \( C^\ast \).

To prove \( |y_1| < C\delta_0 \), let \( \hat{u} = \frac{1}{2} |x|^2 \) be the rotationally symmetric solution to \( L_0[u] = 0 \). As in the proof of Lemma 3.2, let \( w(p, h) \) and \( \hat{w}(p, h) \) be respectively the support functions of \( \Gamma_{h,u} \) and \( \Gamma_{h,\hat{u}} \), where \( p = (\cos \theta, \sin \theta) \). Denote \( t = -h \) (regard \( t \in (-\frac{1}{2}, 0) \) as the time). Then \( w_t(w'' + w) = -1, \hat{w}_t(\hat{w}'' + \hat{w}) = -1 \). Denote \( \varphi = w - \hat{w} \). Direct computation shows that

\[
(w'' + w + \hat{w}'' + \hat{w})\varphi_t = -(w_t + \hat{w}_t)(\varphi'' + \varphi).
\]

Hence \( \varphi \) satisfies the equation

\[
\varphi_t = (w_t\hat{w}_t)(\varphi'' + \varphi).
\]
We have $\hat{w}_t = -\frac{1}{\sqrt{|t|}}$ and by estimate (3.12) (for higher order derivatives), $w_t = -\frac{1+o(1)}{\sqrt{|t|}}$, as $t \to 0$. We obtain $w_t \hat{w}_t = \frac{1+o(1)}{|t|}$. The estimate (3.12) also implies that the curvature of $\Gamma_{u,h}$ is equal to that of $\Gamma_{\hat{u},h}$ up to a lower order perturbation, namely $\varphi'' + \varphi \leq C\delta_0 |t|^{\alpha}$ for some $\alpha > 0$. We obtain $|\varphi_t| \leq C\delta_0 |t|^{\alpha-1}$ and so $|y_1| \leq \sup |\varphi| \leq C\delta_0$.

Next we need a refinement of (3.1).

Lemma 3.3. Let $u$ be an entire convex solution of (1.1) with $\inf u = 0$. Then in an appropriate coordinate system, we have (3.1) with

$$|\varphi(x)| = O(|x|^{2/3}) \quad \text{as} \quad |x| \to \infty.$$  

Proof. Let $u_h(x) = h^{-1}u(h^{1/2}x)$. Then $u_h$ satisfies the equation $L_\sigma[u] = 1$ in $\mathbb{R}^2$ with $\sigma = h^{-1}$. By Theorem 1.3, $u_h$ converges to the function $u^* = \frac{1}{2}|x|^2$, and the level set $\Gamma_{1/2,u_h}$ converges to the unit circle $S^1$ as $h \to \infty$.

For any given sufficiently small constant $\delta_0 > 0$, let $h > 0$ sufficiently large such that

$$\Gamma_{1/2,u_h} \subset N_{\delta_0}(S^1)$$

for some unit circle $S^1$. We claim that for any $\tau > \tau_0$, where $\tau_0 > 3 \max(\delta_0, \sigma)$,

$$\Gamma_{\tau,u_h} \subset \sqrt{2}\tau(N_{\delta_\tau}(S^1))$$

with

$$\delta_\tau \leq C_1(\tau)\sigma^{2/3} + C_2\delta_0 \tau^{\alpha},$$

where $\alpha(N_\delta(S^1)) = N_{\alpha\delta}(\alpha S^1)$, and $\alpha S^1$ is the $\alpha$-dilation of $S^1$ with the same center, the constants $C_1$ and $C_2$ are independent of $\delta_0$ and $h$, and $C_2$ is also independent of $\tau$. The center of the $S^1$ in (3.15) is the minimum point of $u_0$, the solution of $L_0[u] = 1$ in $\Omega_{1/2,u_h}$ satisfying $u_0 = u_h = \frac{1}{2}$ on $\partial\Omega_{1/2,u_h}$.

To prove (3.15), by Lemma 3.2 we have, for any $\tau > 0$,

$$\Gamma_{\tau,u_0} \subset \sqrt{2(\tau + a_0)}(N_{\delta_1}(S^1))$$

with $\delta_1 \leq C\delta_0(\tau + a_0)^{\alpha}$, where $a_0 = -\inf u_0 \geq 0$. By the comparison principle we have $u_0 \leq u_h$ in $\Omega_{1/4,u_h}$. By (3.14) we also have

$$u_0 \geq \frac{1}{2}(|x|^2 - (1 + \delta_0)^2) + \frac{1}{2} \quad \text{in} \quad \Omega_{1/2,u_h}.$$

Hence $a_0 \leq 3\delta_0$.

We will use the following simple result: Let $\Omega$ be a convex domain contained in $B_R$. If the area $|B_R - \Omega| \leq \varepsilon$, then

$$\text{dist}(\partial B_R, \partial \Omega) \leq C\varepsilon^{2/3} R^{-1/3},$$
where \( \text{dist}(A, B) \) denotes the least constant \( \delta > 0 \) such that \( A \subset N_\delta(B) \) and \( B \subset N_\delta(A) \).

We use (3.17) to prove (3.15). Let \( \ell \) be the largest circle, with center at the minimum point of \( u_0 \), contained in \( \Omega_{\tau,u_0} \). Let \( \tilde{\Omega}_{\tau,u} \) be the common area enclosed by \( \Omega_{\tau,u} \) and \( \ell \), and denote \( \Gamma_{\tau,u} = \partial \tilde{\Omega}_{\tau,u} \). Since \( \Omega_{\tau,u} \subset \Omega_{\tau,u_0} \), we have

\[
(3.18) \quad \text{dist}(\Gamma_{\tau,u}, \Gamma_{\tau,u_0}) \leq \text{dist}(\tilde{\Gamma}_{\tau,u}, \ell) + \text{dist}(\ell, \Gamma_{\tau,u_0}).
\]

Since \( \mathcal{L}_0[u_0] = 1 \), we have \( \frac{d}{dt}|\Omega_{\ell,u_0}| = -2\pi \). Hence \( |\Omega_{\tau,u_0}| = 2\pi(\tau + a_0) \). By (3.16), \( \Gamma_{\tau,u_0} \) is in the \( \sqrt{2(\tau + a_0)}\delta_1 = C\delta_0(\tau + a_0)^{1/2+\alpha} \) neighborhood of \( \sqrt{2(\tau + a_0)}S^1 \). Hence

\[
\text{dist}(\ell, \Gamma_{\tau,u_0}) \leq C\delta_0(\tau + a_0)^{1/2+\alpha},
\]

where \( C > 0 \) is independent of \( \delta_0, h, \) and \( \tau \). Recall that \( \Omega_{\tau,u} \subset \Omega_{\tau,u_0} \) and \( |\Omega_{\tau,u_0} - \Omega_{\tau,u}| \leq C\sigma \) by (3.5). Hence by (3.17) we have

\[
\text{dist}(\tilde{\Gamma}_{\tau,u}, \ell) \leq C\sigma^{2/3}(\tau + a_0)^{-1/6}.
\]

Combining (3.16) and (3.18), and noting that \( a_0 \leq 3\delta_0 < \tau \), we obtain (3.15).

Now we fix a \( \tau_0 > 0 \) small such that \( C_2\tau_0^\alpha < 1/4 \). From (3.15) we obtain

\[
(3.19) \quad \Gamma_{\tau_0,u_0} \subset \sqrt{2\tau_0}(N_\delta(S^1))
\]

with \( \delta \leq C\sigma^{2/3} + \delta_0/4 \), where \( C \) is independent of \( \delta_0 \) and \( h \).

Now Lemma 3.3 follows from (3.19) by iteration. We start at the level \( \tau_0^{-k} \) for some sufficiently large \( k \). Denote \( \Omega_k = \sqrt{2\tau_0^{-k}}\Omega_{\tau_0^{-k},u} \) and \( \Gamma_k = \partial \Omega_k \). By (3.1), \( \Gamma_k \) converges to the unit circle as \( k \to \infty \). Suppose \( \Gamma_k \) is in the \( \delta_k \)-neighborhood of \( S^1 \), where \( \delta_k \to 0 \) as \( k \to \infty \). Let \( y_k \) denote the minimum point of the solution of \( \mathcal{L}_0[u] = 1 \) in \( \Omega_{k+1} \) and \( u = \frac{1}{2} \) on \( \Gamma_{k+1} \). By (3.19), \( \Gamma_{k-1} \) is in the \( \delta_{k-1} \)-neighborhood of a unit circle \( S^1 \) centered at \( y_{k-1} \) with

\[
\delta_{k-1} \leq C\tau_0^{2(k-1)/3} + \delta_k/4.
\]

By induction, we obtain

\[
\delta_{k-2} \leq C\tau_0^{2(k-2)/3} + \delta_{k-1}/4.
\]

Hence we have

\[
\delta_j \leq 2C\tau_0^{2j/3} + \delta_k \quad \forall \ j < k.
\]

Let \( k \to \infty \) we obtain

\[
(3.20) \quad \Gamma_j \subset N_{\delta_j}(S^1)
\]

with \( \delta_j \leq 2C\tau_0^{2j/3} \), where \( S^1 \) is centered at \( y_j \). It follows that for \( h = \tau_0^{-j} \) sufficiently large,
with $\delta \leq 2Ch^{-1/6}$, where $S^1$ is centered at $z_j = h^{1/2}y_j$.

Next we estimate $|z_j - z_{j-1}|$. Let $u_j(x) = \tau_0^j u(\tau_0^{-j/2}x)$. Let $v_1$ and $v_0$ be the solutions of $L_0[u] = 1$ which satisfy respectively $v_1 = 1$ on $\{u_j = 1\}$ and $v_0 = \tau_0$ on $\{u_j = \tau_0\}$. By (3.20) we have $\{v_0 = \tau_0\} \subset N_\delta(\sqrt{2}\tau_0 S^1_0)$ and $\{v_1 = \tau_0\} \subset N_\delta(\sqrt{2}\tau_0 S^1_1)$ with $\delta < C\tau_0^{2j/3}$ for some points $p_0$ and $p_1$. As remarked before Lemma 3.3, we may assume $p_0$ and $p_1$ are the minimum points of $v_0$ and $v_1$, so that $z_j = \tau_0^{-j/2}p_1$ and $z_{j-1} = \tau_0^{-j/2}p_0$. By Lemma 3.1 and (3.17) we also have $\{v_0 = \tau_0\} \subset N_\delta(\{v_1 = \tau_0\})$. Hence $|p_0 - p_1| \leq C\delta$. We obtain $|z_j - z_{j-1}| \leq C\tau_0^{j/6}$.

From the above estimate, the sequence \{z_j\} is convergent. Assume that $z_j \to 0$. Then the above estimate implies that $|z_j| \leq C\tau_0^{j/6}$ for any large $j$. Hence for $h = \tau_0^{-j}$,

$$\Gamma_{h,u} \subset N_\delta(\sqrt{2}hS^1),$$

where $\delta \leq Ch^{-1/6}$ and $S^1$ is centered at the origin. It is easy to see the estimate also holds for all $h > 1$. Hence Lemma 3.3 is proved. \square

To finish the proof we need the following fundamental Liouville Theorem by Bernstein [2], see also [24] (p.245).

**Proposition 3.1.** Let $u$ be an entire solution to the elliptic equation

$$(3.21) \quad \sum_{i,j=1}^{2} a_{ij}(x)u_{ij} = 0 \quad \text{in} \quad \mathbb{R}^2.$$ 

If $u$ satisfies the asymptotic estimate

$$(3.22) \quad |u(x)| = o(|x|) \quad \text{as} \quad |x| \to \infty,$$

then $u$ is a constant.

We remark that the operator in the above proposition need not to be uniformly elliptic. Condition (3.21) can be replaced by a weaker condition that $u_{11}u_{22} - u_{12}^2 \leq 0$ and $\not\equiv 0$.

**Proof of Theorem 3.2.** Assume $u$ is locally uniformly convex, namely the Hessian matrix $(D^2u) > 0$ pointwise, which will be proved below. Let $u^*$ be the Legendre transform of $u$. Then $u^*$ satisfies equation (1.9). First we have

$$(3.23) \quad u^*(x) = \frac{1}{2}|x|^2 + O(|x|^{2/3}).$$

Indeed, for any $h > 1$, let $u_h(x) = h^{-1}u(h^{1/2}x)$. Then by Lemma 3.3,

$$u_h(x) = \frac{1}{2}|x|^2 + O(h^{-2/3})$$
in \( B_1(0) \). Denote \( u_h^* \) the Legendre transforms of \( u_h \). Then
\[
u_h^*(x) = \frac{1}{2}|x|^2 + O(h^{-2/3})
\]
in \( B_1(0) \). Observing that \( u_h^*(x) = h^{-1}u^*(h^{1/2}x) \), we obtain (3.23).

Let \( u_0 \) be the unique radial solution of (1.1) satisfying \( u(0) = 0 \), and let \( u_0^* \) denote the Legendre transform of \( u_0 \). Similar to (3.23) we have
\[
u_0^*(x) = \frac{1}{2}|x|^2 + O(|x|^{2/3}).
\]

Write equation (1.9) in the form
\[
G[x, D^2 u^*] =: \det D^2 u^* - \sum (\delta_{ij} - \frac{x_i x_j}{1 + |x|^2}) F_{ij}[u^*] = 1.
\]

Since both \( u^* \) and \( u_0^* \) satisfy equation (1.9), \( v = u^* - u_0^* \) satisfies equation (3.21) in the entire \( \mathbb{R}^2 \) with coefficients
\[
a_{ij} = \int_0^1 G_{ij}[x, D^2 u_0^* + t(D^2 u^* - D^2 u_0^*)]dt,
\]
where \( G_{ij}[x, r] = \frac{\partial}{\partial r_{ij}} G[x, r] \) for any symmetric matrix \( r \). By (3.23) and (3.24), \( |v(x)| = O(|x|^{2/3}) \) as \( |x| \to \infty \). By the above proposition we conclude that \( v \) is a constant. \( \square \)

**Remark 3.3.** When using the Legendre transform we have implicitly used the local uniform convexity of \( u \), namely the Hessian matrix \( \{D^2 u \} > 0 \). In dimension 2, this was proved in [14] by Hamilton’s maximum principle, for high dimensions see [15]. We also note that the reason for using the Legendre transform in the above proof is that equation (3.21) does not involve the first order derivatives.

4. Translating solutions to the level set flow

In this section we prove the case \( \sigma = 0 \) of Theorem 1.2 and that an ancient convex (in space) solution to the mean curvature flow is convex in space-time. We point out that when \( n \geq 4 \), the proof is simpler, see Remark 4.1.

**Theorem 4.1.** For any \( n \geq 2 \) and \( 1 \leq k \leq n \), there exist complete convex solutions, defined in strip regions, to the equation
\[
\sum_{i,j=1}^n (\delta_{ij} - \frac{u_i u_j}{|Du|^2}) u_{ij} = 1
\]
which are not \( k \)-rotationally symmetric. If \( n \geq 3 \), there exist entire convex solutions to (4.1) which are not \( k \)-rotationally symmetric.

By our definition, a function \( u \) is \( k \)-rotationally symmetric if \( u(x) = \phi(|\hat{x}|) \) in an appropriate coordinate system, where \( \hat{x} = (x_1, \cdots, x_k) \). To prove Theorem 4.1 we will need the following logarithm concavity of solutions to (4.1).
Lemma 4.1. Let Ω be a smooth, bounded, convex domain in \( \mathbb{R}^n \). Let \( u \) be the solution of (4.1) in Ω, vanishing on \( \partial \Omega \). Then for any constant \( h \) satisfying \( \inf_{\Omega} u < h < 0 \), the level set \( \Gamma_{h,u} = \{ u = h \} \) is convex. Moreover, \( \log(-u) \) is a concave function.

Proof. Since \( u \) is a solution of (4.1), \( \psi = -\log(-u) \) satisfies

\[
(\delta_{ij} - \frac{\psi_i\psi_j}{|D\psi|^2})\psi_{ij} = e^\psi.
\]

Since \( \psi(x) \to +\infty \) as \( x \to \partial \Omega \), the results in [17] (see §III.12) implies \( \psi \) is convex. Denote

\[
\Omega_{r,t} = \{ x \in \mathbb{R}^n : \frac{|x'|^2}{r^2} + \frac{x_n^2}{t^2} < 1 \},
\]

where \( r, t \) are positive constants, \( x' = (x_1, \cdots, x_{n-1}) \). Let \( u_{r,t} \) denote the solution of (4.1) in \( \Omega_{r,t} \), vanishing on \( \partial \Omega_{r,t} \). Denote \( M_{r,t} = -\inf u_{r,t} \) and \( \Gamma_{r,t} = \{ u_{r,t} = -M_{r,t} + 1 \} \). Obviously \( M_{r,t} \to \infty \) as \( r, t \to \infty \).

The following lemma plays a key role for our construction of non-radial convex solutions. A similar idea was used in [4], where we proved that for any ellipsoid \( E \), there exists an entire convex solution \( u \) to the Monge-Ampère equation \( \det D^2 u = f \) such that \( u(0) = 0 \), \( u \geq 0 \), and the minimum ellipsoid of the sub-level set \( \{ u < 1 \} \) is similar to \( E \).

Lemma 4.2. For any \( \theta > 0 \) and \( K > 1 \), there exist \( r = r(\theta, K) \) and \( t = t(\theta, K) \) such that \( M_{r,t} = K \) and

\[
\sup \{ |x'| : x \in \Gamma_{r,t} \} = \theta \sup \{ x_n : x \in \Gamma_{r,t} \}.
\]

Proof. The solution \( u_{r,t} \) depends continuously on \( r \) and \( t \), and \( M_{r,t} \) is monotone increasing in \( r \) and \( t \). For any \( K > 1 \), we have \( M_{r,t} = K \) when \( r = t = \sqrt{2(n-1)K} \).

It is easy to see that for any fixed \( r > 0 \), \( M_{r,t} \to 0 \) as \( t \to 0 \). Hence for any given \( r > \sqrt{2(n-1)K} \), there exists a unique \( t = t_r < \sqrt{2(n-1)K} \) such that \( M_{r,t} = K \). Moreover we have \( t_r \to 0 \) as \( r \to \infty \). Similarly for any fixed \( t > 0 \), we have \( M_{r,t} \to 0 \) as \( r \to 0 \). Hence for any given \( t > \sqrt{2(n-1)K} \), there exists a unique \( r = r_t < \sqrt{2(n-1)K} \) such that \( M_{r,t} = K \).

Observe that for any fixed \( K \), \( \sup \{ x_n : x \in \Gamma_{r,t} \} \to 0 \) as \( t \to 0 \) and by convexity \( \sup \{ x_n : x \in \Gamma_{r,t} \} \to \infty \) as \( t \to \infty \), where \( r = r_t \) is such that \( M_{r,t} = K \). By the continuity of \( u_{r,t} \) in \( r \) and \( t \), there exist \( r > 0 \) and \( t = t_r \) such that (4.4) holds. □

For any fixed \( \theta \neq 1 \), by Lemma 4.2 there exist \( r = r_k \) and \( t = t_k \) such that \( M_{r_k,t_k} = k \) and (4.4) holds. From the proof of Lemma 4.2 we also have

\[
t_k > r_k \quad \text{if} \ \theta < 1.
\]

36
Hence as $k \to \infty$ we have $t_k \to \infty$ if $\theta < 1$ or $r_k \to \infty$ if $\theta > 1$. Denote $w_k = u_{r_k,t_k} + k$. Then $w_k \geq w_k(0) = 0$. We want to prove $w_k$ converges to a complete solution of (4.1).

We say that a sequence of (embedded) convex hypersurfaces $\{M_k\}$ locally converges to $M$ if for any $R > 1$ and $\delta > 0$, there exists $k_0 > 1$ such that when $k \geq k_0$, $M_k \cap B_R(0) \subset N_{\delta}(M \cap B_R(0))$ and $M \cap B_R(0) \subset N_{\delta}(M_k \cap B_R(0))$, where $B_R$ denotes the ball of radius $R$ and $N_{\delta}$ denotes the $\delta$-neighborhood.

For any fixed integer $j$, by Lemma 4.1, $\varphi_{j,k} = \log j - \log(j - w_k) \ (k \geq j)$ is an even, convex function. Let $M_{j,k}$ denotes the graph of $\varphi_{j,k}$. Observe that for any fixed $j$ and $h$, by (4.4) the sets $M_{j,k} \cap \{x_{n+1} < h\}$ are uniformly bounded in $k$, and can be represented as radial graphs with center at the point $(0, \cdots, 0, \frac{1}{2})$. Hence we may suppose by choosing subsequences that $M_{j,k}$ converges locally to a complete, convex hypersurface $M_j$. Let $\overline{D}_j$ denote the projection of $M_j$ on $\{x_{n+1} = 0\}$ and $D_j$ denote the interior of $\overline{D}_j$. Then $D_j$ is a convex domain and as $k \to \infty$, $\varphi_{j,k}$ converges locally in $D_j$ to a function $\varphi_j$. It follows that $w_k$ converges locally in $D_j$ to a function $w$. Obviously $w$ is a viscosity solution of (4.1) in $D_j$. Repeating the procedure for $j = 1, 2, \cdots$, by the Arzela-Ascoli lemma we obtain a sequence of domains $D_1 \subset D_2 \subset \cdots$ such that $w_k$ sub-converges locally to $w$ in all $D_j$, $j = 1, 2, \cdots$. Let $D = \cup D_j$. Then $D$ is a convex domain and $w_k$ converges locally to $w$ in $D$.

By (4.4), $w$ is not rotationally symmetric. To prove Theorem 4.1, we will prove $w$ is convex and $w(x) \to \infty$ as $x \to \partial D$.

**Lemma 4.3.** For any $x_0 \in \partial D$, we have

\[(4.6) \quad \lim_{x \to x_0} w(x) = \infty.\]

**Proof.** For any fixed $k$, the level set $\{w_k = -t\}$ is a convex solution to the mean curvature flow (with time $t \in (-k, 0)$). For any fixed $t$, by the discussion above we see that $\{w_k = -t\}$ converges to the level set $\{w = -t\}$ as $k \to \infty$. Hence $\{w = -t\}$, where $-\infty < t < 0$, is also a convex solution to the mean curvature flow. It follows that for any $t \in (-\infty, 0)$, $\{w = -t\}$ is smooth and locally uniformly convex. Hence at any time $t \in (-\infty, 0)$, the hypersurface $\{w = -t\}$ is moving at positive velocity. Hence $w(x) \to \infty$ as $x \to \partial D$. \hfill \Box

We can also write the graph of $w_k$ locally in the form $x_n = v_k(x', t)$, where $t = -x_{n+1}$. Then $v_k$ satisfies the non-parametric mean curvature flow equation

\[(4.7) \quad v_t = \sqrt{1 + |Dv|^2} \text{div} \frac{Dv}{\sqrt{1 + |Dv|^2}},\]

where $Dv = (v_{x_1}, \cdots, v_{x_{n-1}})$. Hence if $v$ is convex in $x'$ and if $v_t > 0$ at some point, then $v_t > 0$ everywhere by the Harnack inequality. Using this property one also easily conclude (4.6). We remark that Lemmas 4.2 and 4.3 were also observed by White, see [28].
Lemma 4.4. The solution $w$ is convex.

Proof. Since the level set of $w_k$ is convex, so is the level set of $w$. For any point $y \in D$ and any positive constant $\delta < \min(1, \frac{1}{2}d_y)$, where $d_y = \text{dist}(y, \partial D)$, there exists a constant $M_0 > 0$ depending on $\delta$ such that $\sup\{w(x) : x \in B_\delta(y)\} \leq M_0$ and $\sup\{|Dw(x)| : x \in B_\delta(y)\} \leq M_0$. Denote $v_k = \log(k - w)$. By the concavity of $v_k$ we have

$$|Dv_k(y)| \leq \sup_{x \in \partial B_\delta(y)} \frac{1}{\delta}(|v_k(x) - v_k(y)|) \leq C(\log(k + M_0) - \log(k - M_0)) \leq C/k,$$

where $C > 0$ depends on $M_0$ and $\delta$, but is independent of $k$.

By the concavity of $v_k$, we have furthermore

$$\{\partial_i \partial_j w_k(y)\} = -e^{v_k} \{\partial_i \partial_j v_k + \partial_i v_k \partial_j v_k\} \geq -e^{v_k} \{\partial_i v_k \partial_j v_k\} \geq -\frac{C}{k}I,$$

where $I$ is the unit matrix. Sending $k \to \infty$ we obtain $\{\partial_i \partial_j w(y)\} \geq 0$. Hence $w$ is convex. \hfill \Box

From [12] we know that $\{w = -t\}$ shrinks to a round point as $t \to 0$. Hence $w > 0$ for any $x \neq 0$ and so $w$ is not $k$-rotationally symmetric for any $1 \leq k \leq n$. If we choose $\theta > 1$ sufficiently large, then $w$ must be defined in a strip region by Lemma 2.7. We have thus proved the first part of Theorem 4.1.

We would like to point out that, from the proof of Theorems 1.1 and 1.3, the function $w$ is defined in a strip region for any $\theta > 1$. If $n = 2$, then by Theorem 1.1, $w$ is defined in a strip for any $\theta \neq 1$.

Next we prove the second part of Theorem 4.1. We will prove the solution $w$ obtained above is an entire solution if $n \geq 3$ and $\theta < 1$. Denote

$$r_h = r_{h,w} = \sup\{|x'| : (x', x_n) \in \Omega_{h,w}\},$$
$$t_h = t_{h,w} = \sup\{x_n : (x', x_n) \in \Omega_{h,w}\}.$$

Lemma 4.5. Suppose $t_h \geq \delta r_h$ for some positive constant $\delta > 0$. Then

$$\frac{(\delta r_h)^2}{4(n-1)} \leq h \leq \frac{r_h^2}{2(n-2)}.$$  \hfill (4.8)

Proof. Let

$$\varphi = \frac{1}{2(n-1)}(|x|^2 - \frac{1}{2}(\delta r_h)^2).$$
Then $L_0[\varphi] = 1$ in $\Omega_{h,w} = \{w < h\}$ and $\varphi \geq 0$ on $\partial \Omega_{h,w}$. By the comparison principle it follows that $w - h \leq \varphi$ in $\Omega_{h,w}$. Hence

$$h \geq -\inf \varphi = \frac{(\delta r_h)^2}{4(n-1)}.$$ 

To prove the second inequality of (4.8), let

$$\varphi = \frac{1}{2(n-2)}(|x'|^2 - r_h^2).$$

Then $L_0[\varphi] = 1$ in $\Omega_{h,w}$ and $\varphi \leq 0$ on $\partial \Omega_{h,w}$. It follows $w - h \geq \varphi$ in $\Omega_{h,w}$. Hence

$$h \leq -\varphi(0) = \frac{r_h^2}{2(n-2)}.$$ 

This completes the proof. \qed

Therefore to prove the second part of Theorem 4.1 it suffices to prove that there exists $\delta > 0$ such that

$$(4.9) \quad \sup\{x_n : x \in \Gamma_{h,w}\} \geq \delta \sup\{|x'| : x \in \Gamma_{h,w}\}$$

for any $h > 0$, where $\Gamma_{h,w} = \{w = h\}$. Denote

$$r_{h,k} = \sup\{|x'| : x \in \Gamma_{h,w_k}\},$$

$$t_{h,k} = \sup\{x_n : x \in \Gamma_{h,w_k}\}.$$ 

Then $r_{h,k} |_{h=k} = r_k$ and $t_{h,k} |_{h=k} = t_k$, where $t_k$ and $r_k$ satisfy (4.5). If there is a subsequence of $\{k\}$ such that

$$(4.10) \quad t_{h,k} \geq r_{h,k} \quad \forall \ h \in (0, k),$$

then (4.9) holds with $\delta = 1$ for all $h > 0$. Hence $w$ is defined in the entire space $\mathbb{R}^n$.

If (4.10) is not true, let

$$h_k = \sup\{h > 0 : t_{h,k} < r_{h,k}\}.$$ 

By (4.5) we have $h_k < k$. If the sequence $\{h_k\}$ is uniformly bounded, $w$ is defined in the entire space $\mathbb{R}^n$.

If $h_k \to \infty$, we denote $\bar{w}_k(x) = h_k^{-1}w_k(h_k^{1/2}x)$. Then $L_0[\bar{w}_k] = 1$ in $\{\bar{w}_k < 1\}$ and

$$(4.11) \quad \sup\{|x'| : x \in \{\bar{w}_k < 1\}\} = \sup\{x_n : x \in \{\bar{w}_k < 1\}\}.$$
Observe that the level set \( \{ \tilde{w}_k = -t \} \) is a convex solution to the mean curvature flow (with time \( t \in (-1, 0) \)). From [12] we see that \( \{ \tilde{w}_k = h \} \) shrinks to a round point at \( h \rightarrow 0 \). Hence by (4.11) we have, for any \( h \in (0, 1) \),

\[
(4.12) \quad \sup \{ x_n : x \in \{ \tilde{w}_k = h \} \} \geq \delta \sup \{ |x'| : x \in \{ \tilde{w}_k = h \} \}
\]

for some \( \delta > 0 \) independent of \( h \) and \( k \). Rescaling back we obtain (4.9). This completes the proof of Theorem 4.1.

**Remark 4.1.** When \( n \geq 4 \), we can also construct entire convex solutions of (4.1) as follows. Denote \( \hat{x} = (x_1, \cdots, x_{n-2}), \tilde{x} = (x_{n-1}, x_n) \). Let \( \Omega_{r,t} = \{ x \in \mathbb{R}^n : \frac{|x|^2}{r^2} + \frac{|\tilde{x}|^2}{t^2} = 1 \} \). Let \( u_{r,t} \) be the solution of (4.1) with \( \Omega = \Omega_{r,t} \), which vanishes on \( \partial \Omega \). As before we choose \( r_k \) and \( t_k \) such that \( \inf u_{r_k,t_k} = -k \) and

\[
(4.13) \quad \sup \{ |\hat{x}| : x \in \Gamma_{r,t} \} = \theta \sup \{ |\tilde{x}| : x \in \Gamma_{r,t} \},
\]

where \( \Gamma_{r,t} = \{ u_{r,t} = -k + 1 \} \), and \( \theta \neq 1 \) is any given positive constant. Denote \( w_k = u_{r_k,t_k} + k \). Then \( w_k \) is nonnegative and \( w_k(0) = 0 \). Observe that the function \( \varphi = \frac{1}{2}|\tilde{x}|^2 \)

satisfies the equation \( L_0[\varphi] = 1 \). By the comparison principle we have

\[
(4.14) \quad w_k(x) \leq \frac{1}{2}|x|^2.
\]

Let \( w = \lim_{k \to \infty} w_k \). Then \( w \) satisfies (4.14). Hence by Lemma 4.4, \( w \) is an entire convex solution of (4.1). Obviously \( w \) is not \( k \)-rotationally symmetric for any \( 1 \leq k \leq n \).

**Remark 4.2.** In Lemma 4.4 we showed that a solution to (4.1) is convex if the level set \( \Gamma_h = \{ u = h \} \) is bounded and convex for all large \( h > 0 \). This assertion is true even if \( \Gamma_h \) is unbounded.

**Proposition 4.1.** Let \( u \) be a solution to (4.1) whose graph is a complete hypersurface. Suppose that the level set \( \Gamma_{h,u} \) is convex for any \( h \). Then \( u \) is convex.

**Proof.** If the sub-level sets \( \Omega_{h,u} \) are bounded, Proposition 4.1 is proved in Lemma 4.4. If \( \Omega_{h,u} \) is unbounded, from the proof of Lemma 4.4 it suffices to show that \( \log(h - u) \) is concave for any large constant \( h \). By Lemma 4.1, it suffices to show that for any given \( h > 0 \), \( u \) can be approximated locally in \( \Omega_{h,u} \) by a sequence of solutions to (4.1) whose level sets are bounded and convex.

Let \( \{ D_k \} \) be a sequence of convex domains in \( \mathbb{R}^n \) satisfying \( D_1 \subset D_2 \subset \cdots \), such that \( \cup D_k = \Omega_{h,u} \) for some fixed \( h \). Let \( w_k \) be the solution of (4.1) in \( D_k \) satisfying \( w_k = h \) on \( \partial D_k \). Then \( w_k \geq u \) in \( D_k \) and \( w_k \) is decreasing in \( k \). Hence \( w_k \) converges as \( k \to \infty \) to a solution \( w \) of (4.1) in \( \Omega_h \), satisfying \( w = h \) on \( \partial \Omega_{h,u} \) and \( w \geq u \) in \( \Omega_{h,u} \).

To prove \( w = u \), we need to prove that for any \( h' < h \) (\( h \) fixed), the level sets \( \Gamma_{h',u} \) is sufficiently close to \( \Gamma_{h',u} \). Note that both \( \Gamma_{h',u} \) and \( \Gamma_{h',u} \) evolves by mean curvature (with time \( t = -h' \)), so it suffices to prove \( \Gamma_{h',u} \) is sufficiently close to \( \Gamma_{h',u} \) at infinity.
Let \( \{x_k\} \) be a sequence on \( \Gamma_{h,u} \) with \(|x_k| \to \infty\). By the convexity of \( \Gamma_{h,u} \), the normal of \( \Gamma_{h,u} \) (regarded as a hypersurface in \( \mathbb{R}^n = \{x_{n+1} = h\} \)) at \( x_k \) converges along a subsequence to a boundary point of the Gauss mapping image of \( \Gamma_{h,u} \). Hence after translation, the convex hypersurface \( \Gamma_{h,u} = \{x - x_k : x \in \Gamma_{h,u}\} \) converges to a convex hypersurface which can be split as \( \mathbb{R}^1 \times \Sigma_{h,u} \). Similarly for any \( h' < h \), \( \Gamma_{h',u} = \{x - x_k : x \in \Gamma_{h',u}\} \) converges to a convex hypersurface \( \mathbb{R}^1 \times \Sigma_{h',u} \), and \( \Gamma_{h',w} = \{x - x_k : x \in \Gamma_{h',w}\} \) converges to \( \mathbb{R}^1 \times \Sigma_{h',w} \). By an induction argument on dimension we conclude that \( \Sigma_{h',u} = \Sigma_{h',w} \) for any \( h' < h \). Namely \( \Gamma_{h',w} \) is sufficiently close to \( \Gamma_{h',u} \) at infinity. \( \square \)

5. Translating solutions to the mean curvature flow

In this section we prove the case \( \sigma = 1 \) of Theorem 1.2. That is

**Theorem 5.1.** For any dimension \( n \geq 2 \) and \( 1 \leq k \leq n \), there exist complete convex solutions to equation (1.1), defined in strip regions, which are not \( k \)-rotationally symmetric. If \( n \geq 3 \), there are entire convex solutions to (1.1) which are not \( k \)-rotationally symmetric.

The argument in Section 4 cannot be extended to the mean curvature equation (1.1), as the logarithm concavity in Lemma 4.1 is still an open problem for equation (1.1). To prove Theorem 5.1 we will use the Legendre transform. The purpose to introduce the Legendre transform is to obtain convex solutions to the mean curvature equation (1.1). As remarked at the end of Section 3, we can always assume that a convex solution is locally uniformly convex.

For clarity we divide this section into three subsections. But similarly as in §4, the argument is much more simpler in the case \( n \geq 4 \), see discussions at the beginning of §5.3.

5.1. The Legendre transform

For a smooth, uniformly convex function \( u \) defined in a convex domain \( \Omega \subset \mathbb{R}^n \). The Legendre transform of \( u, u^* \), is a smooth, uniformly convex function defined in the domain \( \Omega^* = Du(\Omega) \), given by

\[
(5.1) \quad u^*(x) = \sup\{x \cdot y - u(y) : y \in \Omega\}.
\]

For example, if \( u(x) = a|x|^2 \), then \( u^*(y) = \frac{1}{4a}|y|^2 \); and if \( u(x) = a|x|^{1+\beta} \), then \( u^*(y) = c|y|^{1+1/\beta} \) with \( c = a\beta/|a(1+\beta)|^{1+1/\beta} \). The function \( u \) can be recovered from \( u^* \) by the same Legendre transform, namely \( u(y) = \sup\{x \cdot y - u^*(x) : x \in \Omega^*\} \). The supremum is attained at the unique point \( y \) which satisfies

\( x = Du(y) \quad \text{and} \quad y = Du^*(x) \).

It follows that the Hessian matrix \( (D^2u) \) at \( y \) is the inverse of the Hessian matrix \( (D^2u^*) \) at \( x \). That is

\[
(5.2) \quad (D^2u) = (D^2u^*)^{-1} = (F^{ij}[u^*])/\det D^2u^*.
\]
where $F_{ij}[u^*]$ is the $(i,j)$-entry of the cofactor matrix of $(D^2u)^*$,

$$F_{ij}[u^*] = \frac{\partial}{\partial r_{ij}} \det r \text{ at } r = D^2u^*.$$  

Hence if $u$ is a uniformly convex solution of (1.2), $u^*$ is a solution of $L^*[u^*] = 1$, where

$$L^*[u^*] = \det D^2u^*/\sum (\delta_{ij} - \frac{x_i x_j}{\sigma + |x|^2}) F_{ij}[u^*]$$

is a fully nonlinear partial differential equation, which is elliptic at convex functions. In particular equation (1.1) is equivalent to the equation

$$L^*[u^*] = 1.$$  

We have the following classical solvability for the Dirichlet problem of equation (5.3).

**Theorem 5.2.** Let $\Omega^*$ be a smooth, uniformly convex domain in $\mathbb{R}^n$ and $\varphi$ be a smooth function defined on $\partial \Omega^*$. Then there is a unique, smooth, uniformly convex solution $u^* \in C^\infty(\overline{\Omega}^*)$ to (5.3) such that $u^* = \varphi$ on $\partial \Omega^*$.

For the proof of Theorem 5.2, we observe that the uniqueness of convex solutions follows from the comparison principle. For the existence of smooth convex solutions, by the continuity method it suffices to establish the global regularity estimates. By Evans and Krylov’s elliptic regularity theory, see, e.g., [6,9,18], it suffices to establish the global second order derivative estimates.

Different proofs for the global second order derivative estimates are available [19, 20, 25]. In [19] Krylov provided a probabilistic proof for (degenerate) Bellman equations. An analytic proof was later given in [20]. Krylov’s estimation covers equation (5.3) as it is equivalent to a concave equation (5.4) below and so can be expressed as a Bellman equation. For Hessian equations (such as (5.4)) the proof in [20] was simplified in [16].

To apply the a priori estimates in [25] we need to write equation (5.3) as a Hessian quotient equation, namely

$$\frac{F_{n}[w]}{F_{n-1}[w]} = \frac{-1}{p_{n+1}}, \quad p \in S^*,$$

where $S^* = \{(x,-1)/(1+|x|^2)^{1/2} : x \in \Omega^*\}$, $S^n$ is the unit sphere,

$$w(p) = (1 + |x|^2)^{-1/2} u^*(x) \quad p = \frac{(x,-1)}{(1 + |x|^2)^{1/2}}, \quad x \in \Omega^*.$$  

If $u^*$ is the Legendre transform of $u$, the function $w$ is indeed the support function of $M_u$ (the graph of $u$), which can also be defined by

$$w(p) = \sup\{p \cdot X : X \in M_u\}.$$
Moreover, $\mathcal{M}_u$ can be recovered from $w$ by $\mathcal{M}_u = \partial K$ with $K = \{X \in \mathbb{R}^{n+1} : p \cdot X \leq w(p) \ \forall \ p \in S^*\}$.

In (5.4) we denote by $F_k[w]$ the $k^{th}$ elementary symmetric polynomial of the eigenvalues $\lambda = (\lambda_1, \cdots, \lambda_n)$ of the matrix $\{\nabla^2 w + wI\}(p)$,

\[(5.6) \quad F_k[w] = \sum_{1 \leq i_1 < \cdots < i_k \leq n} \lambda_{i_1} \cdots \lambda_{i_k}, \quad 1 \leq k \leq n,\]

where $\nabla$ denotes the covariant derivative with respect to a local orthonormal basis on $S^n$, and $I$ is the unit matrix. As the supremum in (5.5) is attained at the unique point $X_p \in \mathcal{M}_u$ with normal $p$, the principal radii of $\mathcal{M}_u$ are equal to the eigenvalues of the Hessian matrix $\{\nabla^2 w + wI\}$ (which also follows from (5.2)). Hence by equation (1.1), $w$ satisfies equation (5.4).

The global second order derivative estimates for Hessian quotient equations in Euclidean domains were established by Trudinger [25]. It is not hard to extend the argument in [25] to equation (5.4) with domains on the unit sphere.

### 5.2. Complete convex solutions

With Theorem 5.2 we can now construct a sequence of convex solutions $(w_k)$ of (1.1), such that $w_k$ converges to a complete convex solution of (1.1) which is not $k$-rotationally symmetric for any $1 \leq k \leq n$.

For any positive constants $r, t$, denote

$$\Omega_{r,t}^* = \{x \in \mathbb{R}^n : \frac{|x'|^2}{r^2} + \frac{x_n^2}{t^2} < 1\},$$

where $n \geq 2, x' = (x_1, \cdots, x_{n-1})$. By Theorem 5.2, the Dirichlet problem

\[(5.7) \quad \left\{ \begin{array}{ll} L^*_1[v] = 1 \quad & \text{in} \ \Omega_{r,t}^*, \\ v = 0 \quad & \text{on} \ \partial\Omega_{r,t}^* \end{array} \right.\]

has a unique smooth convex solution $u_{r,t}^*$. Denote $M_{r,t}^* = -\inf u_{r,t}^*$ and $\Gamma_{r,t}^* = \{x \in \mathbb{R}^n : u_{r,t}^*(x) = -M_{r,t}^* + 1\}$. Then $M_{r,t}^* \to \infty$ as $r, t \to \infty$. Similarly to the proof of Lemma 4.2 we have

**Lemma 5.1.** *For any constants $\theta > 0$ and $K > 1$, there exist $r = r(\theta, K)$ and $t = t(\theta, K)$ such that $M_{r,t}^* = K$ and*

\[(5.8) \quad \sup\{|x'| : x \in \Gamma_{r,t}^*\} = \theta \sup\{x_n : x \in \Gamma_{r,t}^*\}.\]

Now we fix a positive constant $\theta \neq 1$. By Lemma 5.1 there exist positive constants $r = r_k$ and $t = t_k$ such that $M_{r_k,t_k}^* = k$ and (5.8) holds. Similar to (4.5) (after the
Legendre transform the case \( \theta > 1 \) here corresponds to the case \( \theta < 1 \) in Section 4) we have

\[
(5.9) \quad r_k > t_k \quad \text{if} \quad \theta > 1.
\]

Denote \( w^*_k = u^*_{r_k, t_k} + k, \Omega^*_k = \Omega^*_{r_k, t_k} \). Then \( w^*_k \geq w^*_k(0) = 0 \).

Now we use the Legendre transform to change back to equation (1.1). Let \( w^* \) be the Legendre transform of \( w^* \). Then \( w^* \) is a convex function defined in the domain \( \Omega^* = Dw^*(\Omega^*_k) \) and satisfies the mean curvature equation (1.1) in \( \Omega^*_k \).

Let \( u \in C^2(\Omega) \) be a convex solution of (1.1). Suppose \( u(0) = 0 \), \( u \geq 0 \), and \( u \) is an even function. Then for any \( M > 0 \), there exists a constant \( R_0 > 0 \), depending only on \( n \) and \( \theta \), such that \( w^*_k \geq 1 \) on \( \partial B_{R_0}(0) \). Hence

\[
|Dw^*_k| \geq 1/R_0 \quad \text{on} \quad \partial B_{R_0}(0)
\]

and so \( B_{R_0}(0) \subset \Omega^*_k \) for any large \( k \).

\textbf{Lemma 5.2.} Let \( u \in C^2(\Omega) \) be a convex solution of (1.1). Suppose \( u(0) = 0 \), \( u \geq 0 \), and \( u \) is an even function. Then for any \( M > 0 \), there exists a constant \( C > 0 \) such that for any \( y \in \Omega \), if \( u(y) < M \), we have

\[
(5.10) \quad |Du(y)| \leq C.
\]

\textbf{Proof.} Write equation (1.1) in the form

\[
(5.11) \quad \kappa u_\gamma + \frac{u_{\gamma\gamma}}{1 + u^2_\gamma} = 1,
\]

where \( \kappa \) is the mean curvature of the level set \( \{u = const\} \) and \( \gamma \) is the unit outer normal to the level set. The normal \( \gamma(x) \) is a smooth vector field in \( \Omega - \{O\} \). Hence for any point \( y \in \Omega \), there is a smooth curve \( \ell_y \) connecting the origin \( O \) to \( y \) such that \( \gamma(x) \) is tangential to the curve at any point \( x \in \ell_y \). Since \( u \) is an even function, we may suppose \( y \) is in the positive cone \( \{x = (x_1, \cdots, x_n) : x_i \geq 0\} \). It follows by the convexity of \( u \), \( \ell_y \) lies in the positive cone and for any \( x \in \ell_y, \gamma(x) \) is also a point in the positive cone. Hence the arc-length \( L \) of \( \ell_y \) is less than \( n|y| \).

Let \( \psi \) be the restriction of \( u \) on the curve \( \ell_y \), and let \( \ell_y \) be parametrized by the arc-length \( t \). Then we have \( \psi' = u_\gamma \) and \( \psi'' = u_{\gamma\gamma} \). Hence

\[
\frac{\psi''}{1 + \psi'^2} = g(t),
\]

where \( g(t) = 1 - \kappa \psi' \leq 1 \). It follows

\[
\arctg \psi'(t) = G(t) =: \int_0^t g(s)ds,
\]

namely \( \psi'(t) = \tan G(t) \). Hence \( G(L) < \frac{\pi}{2} \) and \( G(L) \geq \frac{\pi}{4} \) if \( \psi'(L) \geq 1 \). Taking integration we have

\[
\psi(L) = \int_0^L \tan G(t)dt.
\]
Denote \( L_0 = \inf \{ t : G(t) \geq \frac{\pi}{4} \} \). Then
\[
  u(y) = \psi(L) \geq \frac{\sqrt{2}}{2} \int_{L_0}^L \frac{1}{\cos G(t)}.
\]
If \( |Du(y)| = \psi'(L) \) is sufficiently large, then \( G(L) \) must be very close to \( \frac{\pi}{2} \). It means \( \psi(L) \) must be very large since \( G'(t) < g(t) < 1 \). Hence Lemma 5.2 is proved. \( \square \)

Note that for the relation \( \psi'' = \frac{\partial u}{\partial y} \gamma \gamma \) we have used the fact that \( \gamma \) is a normal to the level set \( \{ u = \text{const} \} \). If \( \ell_y \) is replaced by an arbitrary curve \( \ell \), then we have
\[
  \psi'' = \frac{\partial u}{\partial y} \gamma \gamma + \kappa \eta,
\]
where \( \gamma \) is a unit vector tangential to \( \ell \), \( \kappa \) is the curvature of \( \ell \), and \( \eta \) is a unit normal to \( \ell \).

Note that by the convexity of \( u \), to prove (5.10) it suffices to consider boundary points. The estimate (5.10) on the boundary of a convex domain can also be obtained by constructing proper sub-solutions (more precisely, solution of \( \frac{u_{tt}}{1+u_t^2} = 1 \) with one variable \( t \)).

**Lemma 5.3.** We have
\[
(5.12) \quad m_k = \inf \{ w_k(x) : x \in \partial \Omega_k \} \to \infty \quad \text{as } k \to \infty.
\]

**Proof.** First observe that for any constant \( h > 0 \), there exists \( R_h > 0 \) (independent of \( k \)) such that for any \( x \in \Omega_k \) with \( |x| > R_h \), we have the estimate
\[
(5.13) \quad w_k(x) \geq h.
\]
In fact this estimate follows from the following geometric property of the Legendre transform: Let \( P_h \) denote the set of linear functions \( g \) such that \( g < w_k^* \) and \( g(0) = -h \). Let \( \overline{\gamma}(x) = \sup \{ g(x) : g \in P_h \} \). Then the graph of \( \overline{\gamma} \) is a convex cone and \( D\overline{\gamma}(\mathbb{R}^n) = \{ w_k \leq h \} \), where \( D\overline{\gamma}(\mathbb{R}^n) \) is the image of the sub-gradient mapping,
\[
  D\overline{\gamma}(\mathbb{R}^n) = D\overline{\gamma}(\{0\}) = \{ p \in \mathbb{R}^n : \overline{\gamma}(x) \geq p \cdot x + \overline{\gamma}(0) \forall x \in \mathbb{R}^n \}.
\]
By (5.8) we have \( |D\overline{\gamma}| < C \). Namely for any \( h > 0 \), the set \( \{ w_k < h \} \) is uniformly bounded. Hence (5.13) holds.

It follows by convexity that for any boundary point \( x_k \in \partial \Omega_k \), we have \( w_k(x_k) \to \infty \) if \( |x_k| \to \infty \). Therefore to prove (5.12) we need only to consider any bounded sequence \( x_k \in \partial \Omega_k \).

However, if \( |x_k| \) and \( w_k(x_k) \) are both uniformly bounded, then by Lemma 5.2, \( y_k = Dw_k(x_k) \in \partial \Omega_k^* \) are also uniformly bounded. Hence by the Legendre transform,
\[
  k = w_k^*(y_k) = x_k \cdot y_k - w_k(x_k)
\]
are also uniformly bounded, a contradiction. \( \square \)
Lemma 5.4. There is a subsequence of \( \{w_k\} \) which converges to a complete convex solution \( w \) of (1.1).

Proof. For any constant \( h > 0 \), by (5.13) the sets \( M_{w_k} \cap \{x_{n+1} < h\} \) are uniformly bounded in \( k \), where \( M_{w_k} \) denotes the graph of \( w_k \). Hence we may suppose by choosing subsequences that \( M_{w_k} \) converges locally to a convex hypersurface \( M \), which is complete by Lemmas 5.2 and 5.3. Let \( \overline{D} \) be the projection of \( M \) on the plane \( \{x_{n+1} = 0\} \) and \( D \) the interior of \( \overline{D} \). Then \( D \) is a convex domain and \( w_k \) converges locally in \( D \) to a convex function \( w \), and \( w \) is a convex solution of (1.1) in \( D \). We claim that \( w(x) \to \infty \) as \( x \to \partial D \). Indeed, if this is not true, then there is a point \( p \in M \) at which the tangent plane of \( M \) is perpendicular to the plane \( \{x_{n+1} = 0\} \). Hence there is a sequence \( p_k = (x_k, w_k(x_k)) \in M_{w_k}, p_k \to p \), such that \( w_k(x_k) \) is uniformly bounded but \( |Dw_k(x_k)| \to \infty \). This is in contradiction with Lemma 5.2. Consequently \( w \) is a complete convex solution of (1.1). By (5.8), \( w \) is not rotationally symmetric.

Now we can prove the first part of Theorem 5.1. Indeed, let \( P \) denote the set of linear functions \( g \) such that \( g < w \) and \( g(0) = -1 \). Let \( \overline{g}(x) = \sup \{g(x) : \ g \in P\} \). Then the graph of \( \overline{g} \) is a convex cone and \( D\overline{g}(\mathbb{R}^n) = \{w^* \leq 1\} \), where \( w^* = \lim_{k \to \infty} w_k^* \) is the Legendre transform of \( w \). Hence if the constant \( \theta > 0 \) in Lemma 5.1 is chosen sufficiently small, then the level set \( \Gamma_{\overline{g}} = \{x \in \mathbb{R}^n : \overline{g}(x) = 1\} \) satisfies

\[
\sup \{|x'| : x \in \Gamma_{\overline{g}}\} = \theta' \sup \{x_n : x \in \Gamma_{\overline{g}}\}
\]

for some \( \theta' > 1 \) sufficiently large. Hence by Lemma 2.7, \( w \) is defined in a strip region.

5.3. Entire convex solutions

Next we prove the second part of Theorem 5.1. We prove that if \( n \geq 3 \) and \( \theta > 1 \), the solution \( w \) obtained in Lemma 5.4 is defined in the entire space \( \mathbb{R}^n \). The following proof is necessary only when \( n = 3 \), since if \( n \geq 4 \), one can construct a sequence of functions \( w_k^* \) as above such that \( w_k^* \), the Legendre transform of \( w_k \), takes the form \( w_k(x) = w_k(|\hat{x}|, |\tilde{x}|) \) (where \( \hat{x} = (x_1, \ldots, x_{n-2}) \), \( \tilde{x} = (x_{n-1}, x_n) \), see Remark 4.1). Then \( w_k(x) \leq \frac{1}{2}|x|^2 \) and so \( \{w_k\} \) sub-converges to an entire convex solution of (1.1).

For any \( h > 0 \), denote

\[
a_{h,k} = \sup \{|x'| : x \in \Gamma_{h,k}\},
\]
\[
b_{h,k} = \sup \{x_n : x \in \Gamma_{h,k}\},
\]

where \( \Gamma_{h,k} = \{w_k = h\} \). Let

\[
\hat{w} = \frac{1}{2(n-2)}(|x'|^2 - a_{h,k}^2) + h,
\]

we have \( L_1[\hat{w}] \geq 1 \). By the comparison principle we have \( w_k \geq \hat{w} \) and so \( \hat{w}(0) \leq 0 \). We obtain \( a_{h,k} \geq (2(n-2)h)^{1/2} \). Sending \( k \to \infty \) we obtain

\[
a_h \geq (2(n-2)h)^{1/2},
\]
where we denote

\[ a_h = \sup \{ |x'| : x \in \Gamma_h \}, \]
\[ b_h = \sup \{ x_n : x \in \Gamma_h \}, \]

where \( \Gamma_h = \{ w = h \} \). To prove that \( w \) is an entire solution, it suffices to prove

\[ (5.16) \quad b_h \to \infty \quad \text{as} \quad h \to \infty. \]

To prove (5.16) we use Lemma 2.7. That is if there exist \( h_0 > 1 \) and \( \beta > 0 \) sufficiently small, such that \( b_{h_0,k} \leq \beta h_1^{1/2} \), then there exists a constant \( C > 0 \) independent of \( k \), such that \( b_{h,k} \leq C \) for all \( h \in (1, m_k) \), namely \( w_k \) is defined in the strip \( \{ |x_n| < C \} \), where \( m_k \) is the constant in (5.12).

It follows that if \( b_{h,k} \geq \beta \hat{h}^{1/2} \) for some large \( \hat{h} > 1 \), then there exists \( \delta > 0 \), independent of \( \hat{h} \) and \( k \), such that \( b_{h,k} \geq \delta h^{1/2} \) for all \( 1 < h < \hat{h} \). Therefore to prove \( w \) is an entire solution, it suffices to prove that there exists a constant \( \beta > 0 \) independent of \( k \), and a sequence \( \tau_k \), where \( \tau_k \leq m_k \) and \( \tau_k \to \infty \) as \( k \to \infty \), such that

\[ (5.17) \quad b_{\tau_k,k} \geq \beta \tau_k^{1/2}. \]

Denote

\[ (5.18) \quad r_{h,k} = \sup \{ |x'| : x \in \Gamma_{h,k}^* \}, \]
\[ t_{h,k} = \sup \{ x_n : x \in \Gamma_{h,k}^* \}, \]

where \( \Gamma_{h,k}^* = \{ w_k^* = h \} \). We have

**Lemma 5.5.** Suppose \( r_{h,k} \geq t_{h,k} \). Then we have the estimates

\[ (5.19) \quad \sqrt{h/n} \leq r_{h,k} \leq \sqrt{2h}. \]

**Proof.** The function

\[ v = h + \frac{n}{2}(|x|^2 - 2r_{h,k}^2) \]

is a sub-solution of (5.3), namely \( \mathcal{L}_1^* [v] \geq 1 \). Moreover, since \( r_{h,k} \geq t_{h,k} \), we have \( v \leq h \) on \( \{ w_k^* = h \} \). Hence by the comparison principle, \( v \leq w_k^* \). In particular we have \( 0 = w_k^*(0) \geq v(0) = h - nr_{h,k}^2 \). The first inequality of (5.19) is proved.

Next observe that when \( n \geq 3 \), the function

\[ v = h + \frac{1}{2}(|x'|^2 - r_{h,k}^2) + K x_n^2 \]

47
is a super-solution of (5.3), namely $L_1[v] ≤ 1$, for any $K > 1$. For any $ε > 0$ we can choose $K$ sufficiently large such that $v > w^*_k - ε$ on $\{w^*_k = h\}$. Hence $v(0) ≥ w^*_k(0) = 0$ and we obtain the second inequality.

We remark that $L_1[u^*] ≥ 1$ ($≤ 1$, resp.) is equivalent to $L_1[u] ≤ 1$ ($≥ 1$, resp.), where $u^*$ is the Legendre transform of $u$.

**Proof of Theorem 5.1.** The first part of Theorem 5.1 has been proved in §5.2. We need only to prove that when $n ≥ 3$ and $θ > 1$, $w$ is an entire solution. It suffices to prove (5.17).

By (5.9) we have $r_{h,k} ≥ t_{h,k}$ when $h$ is close to $k$. If $r_{h,k} ≥ t_{h,k}$ for all $h < k$, then by (5.19) we have

\[ \frac{1}{2}|x'|^2 ≤ w^*_k(x', 0) ≤ n|x'|^2. \]

By the Legendre transform we have

\[ \frac{1}{4n}|x'|^2 ≤ w_k(x', 0) ≤ \frac{1}{2}|x'|^2. \]

Sending $k → ∞$ we obtain

\[ \frac{1}{4n}|x'|^2 ≤ w(x', 0) ≤ \frac{1}{2}|x'|^2. \]

Hence

\[ a_h ≤ (4nh)^{1/2} \quad ∀ h > 1. \]

By Lemma 2.6, $a_h b_h ≥ Ch$ ($a_h$ and $b_h$ here correspond to $\overline{a}_h$ and $\overline{b}_h$ in Lemma 2.6). Hence $b_h → ∞$ as $h → ∞$, namely $w$ is defined in the whole space $\mathbb{R}^n$.

If there exists $h > 0$ such that $r_{h,k} < t_{h,k}$, we denote

\[ h_k = \inf\{h : r_{h',k} ≥ t_{h',k} \quad ∀ h < h' < k\}. \]

If $\{h_k\}$ is uniformly bounded, or contains a uniformly bounded subsequence, then (5.20), and so also (5.21), holds for $|x'|$ large. Hence $w$ is also an entire solution.

Finally we consider the case $h_k → ∞$ as $k → ∞$. Denote $G^*_k = \{w^*_k < h_k\}$ and $G_k = Dw^*_k(G^*_k)$. We consider the solution $w_k$ in the domain $G_k$. Denote

\[ τ_k = \inf\{w_k(x) : x ∈ ∂G_k\}. \]

Since $h_k → ∞$, similarly to Lemma 5.3 we have $τ_k → ∞$ as $k → ∞$. Denote $\tilde{G}^*_k = \frac{1}{h_k} G^*_k$, $\tilde{G}_k = \frac{1}{h_k} G_k$, and

\begin{align*}
\tilde{w}^*_k(x) &= \frac{1}{h_k} w^*_k(\sqrt{h_k} x), \\
\tilde{w}_k(x) &= \frac{1}{h_k} w_k(\sqrt{h_k} x).
\end{align*}

(5.24)
Then \( \hat{w}_k \) is the Legendre transform of \( \hat{w}_k^* \), and

\[
(5.25) \quad c_k =: \inf \{ \hat{w}_k(x) : x \in \partial \hat{G}_k \} = \tau_k / h_k.
\]

We claim

\[
(5.26) \quad c_k \leq 4n \quad \forall \ k.
\]

Indeed, by (5.22), \( \hat{G}_k^* \) has a good shape, namely

\[
(5.27) \quad \sup \{|x'| : x \in \hat{G}_k^* \} = \sup \{x_n : x \in \hat{G}_k^* \}.
\]

As the domain \( \hat{G}_k^* \) is rotationally symmetric with respect to \( x' \), by Lemma 5.5 and (5.27) we have \( \hat{G}_k^* \subset B_2(0) \). Note that \( \hat{w}_k^* \) is the Legendre transform of \( \hat{w}_k \), we have \( D\hat{w}_k(\hat{G}_k) = \hat{G}_k^* \).

Hence

\[
(5.28) \quad |D\hat{w}_k| \leq 2 \quad \text{in} \quad \hat{G}_k.
\]

Since \( \hat{G}_k^* \subset B_2(0) \), there exists \( r \leq 2 \) such that \( \hat{G}_k^* \subset B_r(0) \), and \( \partial \hat{G}_k^* \) and \( \partial B_r(0) \) have a common boundary point \( x_0 \). Observe that \( v = 1 + \frac{n}{2}(|x|^2 - r^2) \) is a sub-solution of (5.3) and \( v \leq \hat{w}_k^* = 1 \) on \( \partial \hat{G}_k^* \), we have \( |D\hat{w}_k^*(x_0)| \leq |Dv(x_0)| \leq 2n \). By the Legendre transform, \( y_0 = D\hat{w}_k^*(x_0) \) is a boundary point of \( \hat{G}_k \). Since \( \hat{w}_k^* \) is constant on \( \partial \hat{G}_k^* \), one easily verifies that the domain \( \hat{G}_k = D\hat{w}_k^*(\hat{G}_k^*) \) is star-shaped. By (5.28) we obtain

\[
\hat{w}_k(y_0) \leq |y_0| \sup |D\hat{w}_k| \leq 4n,
\]

namely (5.26) holds.

Denote

\[
\varepsilon_k = \inf \{x_n > 0 : \hat{w}_k(0, \ldots, 0, x_n) \geq c_k \} = \sup \{x_n : \hat{w}_k(x', x_n) \leq c_k \}.
\]

Then by (5.26) and the rescaling (5.24), to prove (5.17) it suffices to prove that \( \varepsilon_k \) has a uniform positive lower bound, namely

\[
(5.29) \quad \varepsilon_k \geq \varepsilon_0 > 0 \quad \forall \ k
\]

We prove (5.29) as follows. Observing that \( \hat{w}_k^*(0) = 0 \), \( \hat{w}_k^* = 1 \) on \( \partial \hat{G}_k^* \), and \( \hat{G}_k^* \subset B_2(0) \), we have \( |D\hat{w}_k^*| \geq 1/2 \) on \( \partial \hat{G}_k^* \). That is \( \hat{G}_k \supset B_{1/2}(0) \) for all \( k \). By (5.28) we may suppose \( \hat{w}_k \to \hat{w} \) in \( B_{1/2}(0) \). Then \( \hat{w} \geq 0 \), \( \hat{w}(0) = 0 \), and \( |D\hat{w}| \leq 2 \) in \( B_{1/2}(0) \). Since \( \hat{w}_k \) satisfies the equation \( \mathcal{L}_\sigma[v] = 1 \) in \( \hat{G}_k \), where \( \sigma = 1/h_k \), and \( \mathcal{L}_\sigma \) is the operator in (1.2). By Lemma 2.5, \( \hat{w} \) is a solution of

\[
(5.30) \quad \mathcal{L}_0[v] = 1 \quad \text{in} \quad B_{1/2}(0).
\]
If \( \dot{w}(x) > 0 \) for any \( x \neq 0 \), then \( c = \inf \{ \dot{w}(x) : |x| = 1/2 \} > 0 \). Hence \( c_k \geq \frac{1}{2} c \) for sufficiently large \( k \). By (5.28) we then have \( \varepsilon_k \geq c_k/2 \geq c/4 \) for large \( k \). Hence (5.29) holds.

If the convex set \( \{ \dot{w} = 0 \} \) contains a line segment \( \ell \), then \( \ell \) is either contained in the \( x_n \)-axis, or in the plane \( \{ x_n = 0 \} \), as the function \( \dot{w} \) is rotationally symmetric with respect to \( x' \) and symmetric in \( x_n \). Furthermore, by the comparison principle, the set \( \{ \dot{w} = 0 \} \) contains no interior points, i.e. the Lebesgue measure \( |\{ \dot{w} = 0 \}| = 0 \). Note that the origin is the middle point of \( \ell \) as \( \dot{w} \) is an even function.

In the former case, namely if \( \ell \) is contained in the \( x_n \)-axis, we have \( \dot{w}(x) > 0 \) for any point \( x \in \partial B_{1/2}(0) \) not lying on the \( x_n \)-axis, for otherwise \( \dot{w} = 0 \) on a set with interior points. Hence
\[
c_k \geq \inf_{\partial Q} \dot{w}_k(x) = \dot{w}_k(0, \cdots, 0, d/2),
\]
where \( Q = \{ x \in \mathbb{R}^n : |x'| < \frac{d}{2}, |x_n| < \frac{d}{2} \} \), where \( d \) is the arclength of \( \ell \). Hence we have \( \varepsilon_k \geq \frac{d}{2} \) and (5.29) holds.

We claim the latter case, namely the case when the line segment \( \ell \) is contained in the plane \( \{ x_n = 0 \} \), does not occur. Indeed, if \( \ell \subset \{ x_n = 0 \} \), then \( \{ \dot{w} = 0 \} \) is a disc type set \( D = \{ x \in B_{1/2}(0) : |x'| < d, x_n = 0 \} \) for some \( d > 0 \). Since the set \( \{ \dot{w} = 0 \} \) contains no interior points, the level set \( \{ x \in \mathbb{R}^n : \dot{w}(x) = h \} \) is contained in a strip \( \{|x_n| < \delta\} \) with \( \delta \to 0 \) as \( h \to 0 \). Therefore if \( h > 0 \) is sufficiently small, there exist points on the level set \( \{ \dot{w} = h \} \) at which the mean curvature \( \kappa \) of \( \{ \dot{w} = h \} \) is sufficiently small. Write equation (5.30) in the form \( \kappa |D\dot{w}| = 1 \) (see (2.2) with \( \sigma = 0 \)), we find that \( |D\dot{w}| \) is very large. On the other hand we have \( |D\dot{w}| \leq 2 \) by (5.28). We reach a contradiction. Hence the latter case does not occur. This completes the proof. \( \square \)

6. Applications to the mean curvature flow

First we consider applications of Theorem 1.1. For a mean convex flow \( \mathcal{M} = \bigcup_{t \in [0,T]} \mathcal{M}_t \) in \( \mathbb{R}^{n+1} \), let \( \mathcal{F} \) denote the set of all limit flows (namely blowup solutions) to \( \mathcal{M} \) before first time singularity. A key result in [27] is that a limit flow in \( \mathcal{F} \) cannot be a hyperplane of multiplicity two, from which it follows that the “grim reaper” \( x_{n+1} = \log \sec x_1 \) can not be a limit flow in \( \mathcal{F} \), see [28, 30]. As indicated in the introduction, we will consider solutions with positive mean curvature only.

**Corollary 6.1.** A flow \( \mathcal{M}' \in \mathcal{F} \) (with positive mean curvature at some point) must sweep the whole space \( \mathbb{R}^{n+1} \).

**Proof.** By Proposition 4.1, \( \mathcal{M}' \) is a graph in space-time (with \( x_{n+2} = -t \)) of a convex function \( u \) on a convex domain in \( \mathbb{R}^{n+1} \), and \( u \) is a complete convex solution of (1.2) with \( \sigma = 0 \). If \( u \) is not defined in the entire \( \mathbb{R}^{n+1} \), by Corollaries 2.1 and 2.2, \( u \) is defined in a strip region of the form \( \{ x \in \mathbb{R}^{n+1} : |x_{n+1}| < C \} \) (in appropriate coordinates). By Lemma
2.6, the projection of \( \{ u = h \} \) on the \( x' = (x_1, \ldots, x_n) \) plane contains the ball \( \{|x'| < Ch\} \) for some \( C > 0 \) independent of \( h \geq 1 \). It follows that the tangent flow at infinity to the solution \( u \) (more precisely, there is a limit flow to the original mean convex flow which) is a multiplicity 2 plane, see Corollary 12.5 in [27] or Corollary 4 in [28]. But a multiplicity 2 plane does not occur as a limit flow in \( \mathcal{F} \). Hence \( u \) must be defined in the whole \( \mathbb{R}^{n+1} \). □

If a convex translating solution \( M' \) is a limit flow to a mean convex flow in \( \mathbb{R}^3 \), then \( M' \) is the graph of a convex function \( u \) satisfying (1.1). By Corollary 6.1, \( u \) is defined in the whole \( \mathbb{R}^2 \). By Theorem 1.1, \( u \) is rotationally symmetric. We obtain Corollary 1.1.

From the case \( \sigma = 0 \) in Theorem 1.1, we also have the following

**Corollary 6.2.** A convex solution to the curve shortening flow which sweeps the whole space \( \mathbb{R}^2 \) must be a shrinking circle.

From Theorem 1.2, there exist closed convex solutions to the curve shortening flow which are not the shrinking circle.

Next we consider applications of Theorem 1.3. First we have

**Corollary 6.3.** Let \( M = \{ M_t \} \) be an ancient convex solution to the mean curvature flow. Let \( M'_t = \{ x \in \mathbb{R}^{n+1} : (-t)^{1/2} x \in M_t \} \) be a dilation of \( M_t \). Then \( M'_t \), after a proper rotation of coordinates, converges as \( t \to -\infty \) to one of the following

(i) an \( n \)-sphere of radius \( \sqrt{2n} \);
(ii) a cylinder \( S^k \times \mathbb{R}^{n-k} \), where \( S^k \) is a \( k \)-sphere of radius \( \sqrt{2k} \);
(iii) the plane \( \mathbb{R}^n \) of multiplicity two.

**Proof.** By Proposition 4.1, \( M \) is the graph in space-time of a convex function \( u \) in \( \mathbb{R}^{n+1} \) satisfying equation (1.2) with \( \sigma = 0 \). If \( u \) is an entire solution, (iii) does not occur and Corollary 6.3 is equivalent to Theorem 1.3. If \( u \) is not an entire solution, by Corollaries 2.1 and 2.2, \( u \) is defined in a strip region. As in the proof of Corollary 6.1, the projection of \( M_t = \{ u = -t \} \) on the \( x' \)-plane contains the ball \( \{|x'| < C|t|\} \), by convexity we see that \( M'_t \) converges to a plane. □

From Theorem 1.3 (the case \( \sigma = 0 \)) we also obtain

**Corollary 6.4.** Let \( M = \bigcup_{t \in [0,T]} M_t \) be a mean convex flow in \( \mathbb{R}^{n+1} \). Suppose \( h_i \to \infty \) and \( p_i \in M_{t_i} \), such that the blow-up sequence \( M_i = \{(h_i(p - p_i), h_i^2(t - t_i)) : (p, t) \in M\} \) converges to an ancient convex solution. Then there exist \( h'_i \to \infty \) such that the corresponding blow-up sequence \( M'_i = \{(h'_i(p - p_i), h'_i^2(t - t_i)) : (p, t) \in M\} \) converges along a subsequence to a shrinking sphere or cylinder.

At type II singularity, from Theorem 1.3 (the case \( \sigma = 1 \)) we have

**Corollary 6.5.** Let \( M_i \) be as in Corollary 6.4. If \( M_i \) converges to a convex translating solution, then there is a sequence of positive constants \( \lambda_i \to 0 \) such that, in a proper coordinate
system, the blow up sequence \( \tilde{M}_i = \{(\lambda_i x_1, \cdots, \lambda_i x_n, \lambda_i^2 x_{n+1}, \lambda_i^2 t) : (x_1, \cdots, x_{n+1}, t) \in M_i \} \) converges to the flow \( M' = \{(x, \eta_k(x) + t) \in \mathbb{R}^{n+1} : x \in \mathbb{R}^n, t \in \mathbb{R}\} \), where \( \eta_k \) is given in (1.4).

In Corollaries 6.3-6.5, we need not to restrict ourself to limit flows in \( \mathcal{F} \).

As indicated in the Introduction, our Theorem 1.3 corresponds to Perelman’s classification of ancient \( \kappa \)-noncollapsing solutions with nonnegative sectional curvature to the 3-dimensional Ricci flow [22]. Indeed, Theorems 2.1 and 2.2 implies that the set of entire, ancient convex solutions in \( \mathbb{R}^{n+1} \), which includes all limit flows in \( \mathcal{F} \) by Corollary 6.1, is compact if one normalizes the solutions such that their mean curvature equals one at some fixed point, say the origin. To see this, let \( M = \{M_i\} \) be an ancient convex solution. Then \( M \) is the graph in space-time of an entire convex function \( u \). If the mean curvature of \( M \) equals one at the origin, then \( |Du(0)| = 1 \), and so the compactness follows from Theorems 2.1 and 2.2.

For ancient convex solutions in \( \mathbb{R}^3 \), we have the following

**Corollary 6.6.** Let \( M = \{M_i\} \) be an ancient convex solutions which is a limit flow to a mean convex flow in \( \mathbb{R}^3 \). Suppose at time \( t = 0 \), the time slice \( M_0 = \{u = 0\} \) is noncompact. Then \( \forall \varepsilon > 0 \), there is a compact set \( G \) such that any point in \( M_0 \setminus G \) has a neighborhood which is, after normalization, \( \varepsilon \)-close (see (2.56)) to the cylinder \( S^1 \times \mathbb{R}^1 \).

**Proof.** As indicated above, \( M \) is the graph in space-time of a convex function \( u \) defined in the whole \( \mathbb{R}^3 \). If the level sets \( \{u = h\} \) is a cylinder, then \( u \) is a convex function of two variables and Corollary 6.6 follows from Theorem 1.1. In this case the set \( G = \emptyset \). Otherwise by convexity we may assume by choosing an appropriate coordinate system that \( u(0) = 0 \), \( u \geq 0 \) in \( \{x_1 \leq 0\} \), and \( u \leq 0 \) on the positive \( x_1 \)-axis. For \( a \in (0, \infty) \), let \( x_a \) be the point such that \( u(x_a) = \inf \{u(x) : x_1 = a\} \). If \( \inf u \) is bounded, let \( u_a(x) = u(x + x_a) - u(x_a) \). By the convexity of \( u \), \( |Du(x_a)| \) is decreasing as \( a \to \infty \), so it is uniformly bounded. By the above mentioned compactness result (Theorem 2.1), \( u_a \) sub-converges to a convex function \( u_0 \). By our choice of coordinates, we have \( u_0 \leq 0 \) on the positive \( x_1 \)-axis. But since \( \inf u \) is bounded, we have \( u_0 = 0 \) on the positive \( x_1 \)-axis. By Lemma 2.9 it follows that \( u_0 \) is independent of \( x_1 \). That is \( u_0 \) is a function of \( x_2 \) and \( x_3 \). By Theorem 1.1, \( u_0 \) is rotationally symmetric in \( x_2 \) and \( x_3 \).

If \( \inf u = -\infty \), then \( u(x_a) \to -\infty \) as \( a \to \infty \). By the compactness Theorem 2.1, the sequence \( u_a(x) = \frac{1}{h_a}[u(\sqrt{h_a}x + x_a) - u(x_a)] \), where \( h_a = |u(x_a)| \), converges along a subsequence to a convex solution \( u_0 \) of (4.1). Since \( |Du(x_a)| \) is uniformly bounded, we see that \( u_0 = 0 \) on the positive \( x_1 \)-axis, see (2.49). By Lemma 2.9 it follows that \( u_0 \) is independent of \( x_1 \). By Theorem 1.1, \( u_0 \) is rotationally symmetric in \( x_2 \) and \( x_3 \). \( \square \)

By a compactness argument, one easily sees that the diameter of \( G \) is uniformly bounded if the maximum of the mean curvature of \( M_0 \) is equal to 1. We remark that by Theorem 1.2, Corollary 6.6 is not true for convex solutions in \( \mathbb{R}^n \) for \( n \geq 4 \). But in high dimensions
we have accordingly Corollary 6.3, which says that an ancient convex solution behaves asymptotically as $t \to -\infty$ like a sphere or cylinder. Note that for any dimension $n \geq 2$, the set $\mathcal{F}$ contains all blowup solutions before the first time singularity, and that the blowup sequence converges smoothly on any compact sets to an ancient convex solution [28]. Therefore similarly as in [23], one may infer that $\mathcal{M} = \{M_t\}$ is a mean convex flow, then at any point $x_t \in M_t$ with large mean curvature before the first time singularity, $M_t$ satisfies a canonical neighborhood condition. If $n = 2$, the condition is very similar to that in [23]. In high dimensions, the condition is more complicated. We will not get into details in this direction. Concerning the geometry of singularity set it would be more interesting if one can prove the following

**Conjecture.** Let $K$ be a smooth and compact domain in $\mathbb{R}^{n+1}$. Suppose the boundary $\partial K$ has positive mean curvature. Let $\mathcal{M} = \cup_t M_t$ be the solution to the mean curvature flow with initial condition $\partial K$. Then

(i) singularity occurs only at finitely many times;
(ii) at each singular time the singularity set consists of finitely many connected components;
(iii) each connected component is contained in a $C^1$ smooth $(n-1)$-submanifold (with or without boundary). If $n = 2$, each component is either a single point or a $C^1$ curve.

One may wish to assume $n < 7$, but the conjecture is likely to be true for all $n \geq 2$, as the second order derivative estimates for (4.1) may hold for any $n \geq 2$.

We conclude this paper with some interesting questions related to our Theorems 1.1-1.3. For Theorem 1.1 a question is whether an entire solution of (1.1) in $\mathbb{R}^2$ is convex. For Theorem 1.2 a question is whether a convex solution $u$ of (1.1) is rotationally symmetric if $|Du(x)| \to \infty$ as $|x| \to \infty$. We expect affirmative answers to both questions.

For Theorem 1.3, an interesting question is whether a non-rotationally symmetric ancient convex solution can occur as a limit flow in $\mathbb{R}^n$. We believe that any limit flow to a mean convex flow at isolated singularities in space-time is rotationally symmetric, otherwise non-rotationally symmetric convex limit flow may occur if the following situations arise: (a) if there exists a mean convex flow in $\mathbb{R}^n$ ($n \geq 4$) which develops first time type $\mathbb{I}$ singularities simultaneously on a non-smooth curve (say a polygon) in a 2-plane; (b) if a mean curvature flow in $\mathbb{R}^n$ ($n \geq 4$) develops first time singularity on a smooth curve, and the singularity is type $\mathbb{I}$, except one type $\mathbb{I}$ singular point. In case (a) we expect a non-rotationally symmetric convex translating solution at the vertices of the polygon. In case (b) a blowup solution near the type $\mathbb{I}$ singular point may not be rotationally symmetric.
